PRACTICE IN BRITISH SOUTH AFRICA.

To the Editors of THE LANCET.

SIRS,—Can any of your readers give me any information concerning medical practice in South Africa? And also if the field there be already fully supplied.

May 18th, 1895.

I am, Sirs, yours truly,
M.B.

MEDICAL ADVERTISING AT HARROGATE.

THE Harrogate Advertiser of May 25th contains the advertisement of Dr. Roberts's book, price 6d., with quotations from our own review. This is an undesirable way of announcing his "discussion on the therapeutics of the Harrogate waters." Another practitioner in the same paper has the following paragraph, which, we are informed, has appeared repeatedly:—

"Dr. — requests us decisively to contradict the rumour which has reached him from several sources that, having taken a partner, he contemplates retiring from practice in Harrogate. Dr. — disclaims any such intention."

Mr. L. King.—We do not prescribe or recommend individual practitioners.

THE PATIENT'S LEISURE AND THE DOCTOR'S HASTE.

THE Leicester Post gives an account of a baby fed on biscuits and finally on bread-sop. Very naturally the baby died. When the child was dying a medical man, Mr. Dodd, was sent for in a hurry. A second message had to be sent before he arrived, to find the child in coma with convulsions. The foreman of the jury before which the case was investigated thought the medical man should have attended sooner. Mr. Dodd very reasonably remarked that a practitioner's time was not his own. Other cases claimed yet earlier attention. He thought in such cases parents should call the nearest medical man first and their own afterwards. The real moral of this case is that parents should have far more medical advice, and should seek it much sooner than they do. It is of no use to wait till death is imminent and then to blame the practitioner because he does his work in order. This child's life might have been saved if the mother had taken the advice of a medical man with regard to the elementary points in feeding a baby. The foreman of the jury should have given his censure a different direction.

Trachea.—Will this correspondent kindly send us his address, which has been mislaid?

A HINT TO THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—It would seem an opportune time to suggest through the medium of THE LANCET to the General Medical Council the glaring anomaly that though quacks are being extirminated, yet the vendors of patent remedies flourish broadcast throughout our land. Can the General Medical Council not interfere? Patent remedies are regarded by the medical profession as the productions of quacks. Why, then, cannot their sale be prohibited by law?

To me even a stranger anomaly exists. When medical classes are being announced in the local papers as about to begin the names of the professors or lecturers on their respective specialties are advertised side by side with the vaunted medicine mongers, advertising dentists, curers of piles, &c. Honourable and leading professional men must blush to read such advertisements of their calling in the daily papers, yet they wink at it, and abide by it.

I am, Sirs, yours faithfully,

May 19th, 1895.

MEDICUS.

THE LIBELLING OF A PROFESSION.

Reynolds's Newspaper declines to withdraw its suggestion that the medical profession arranges with friends without the patients' consent for the death of said patients with incurable disease—a suggestion couched in the most libellous terms, and itself a libel on a profession which prolongs such lives to the utmost limit. So much the worse for Reynolds's Newspaper. It will suffer more than the profession.

"SELF-PROPELLING" CHAIRS.

A CORRESPONDENT writes:—

"Can any of your readers advise as to a self-propelling chair for a patient suffering from paraplegia? He has good strength in the back and arms, but has lost a foot. One such as he might use out-of-doors as well as indoors is desirable. He already has a 'Merlin,' but the driving arrangement in this hurts his hands and tears his coat sleeves and gloves."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—

Glasgow Herald, Lincolnshire Echo, Brighton Gazette, Hobart Mercury, Newcastle Chronicle, Leicester Post, Oldham Standard, North Cheshire Herald, Kent County Examiner, Birmingham Gazette, Derbyshire Times, Manchester Courier, Bradford Observer, Liverpool Echo, Citizen, Builder, Cork Constitution, Derby Reporter, Leeds Mercury, Scotsman, Architect, Reicar and Saltburn-by-the-Sea Gazette, Bristol Mercury, Alnwick Gazette, Times of India, Pioneer Mail, Morning, Yorkshire Post, Werthing Intelligencer, Liverpool Daily Post, Boston Independent, Sanitary Record, West Midlands Standard, City Press, Weekly Free Press and Aberdeen Herald, Surrey Advertiser, Star, Reading Mercury, Lincoln Gazette, Stroud News, Hertfordshire Mercury, Reynolds's Newspaper, Mining Journal, Buchan Observer, Chester Courant, Darlington Echo, Crewe Guardian, St. Bartholomew's Hospital Journal, Manchester Guardian, Worcester Daily Times, Manchester Evening News, Southampton Observer, Lincolnshire Chronicle, Rochdale Observer, Grays Standard, Blackpool Gazette, Craven Herald, Cape Times, Buxton Herald, Gravesend Standard, Westmeath Examiner, Rangoon Gazette, North China Daily News, Apr Observer, Durham Mercury, Berwick Journal, Auckland Chronicle, Ulverston Advertiser, Montreal Daily Star, Melbourne Argus, Madras Times, Southport Visitor, Nurses' Journal, &c. &c.

Communications, Letters &c. have been received from—

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Office letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Amiens, Paris.

An Address

ON

THE MEDICAL HISTORY OF MR. AND MRS. SAMUEL PEPYS.

Read before the Abernethian Society on March 6th, 1895.¹By D'ARCY POWER, M.B. OXON., F.R.C.S. ENG.,
SURGEON TO THE VICTORIA HOSPITAL FOR CHILDREN.

MR. PRESIDENT AND GENTLEMEN,—Some of you may perhaps think that I owe the society an apology for bringing before it such a paper as that which I propose to read. I do not think so. The older we get and the more the cares of this world threaten us, the more necessary is it to have a hobby. We need not ride it so as to be a nuisance to our friends, but in reason we are better for it; and if, as in my case, the hobby leads us to become intimately acquainted with the manner of life and thoughts of a bygone age, it is, I humbly conceive, an advantage. We are too apt to think that everything at the present day has reached its acme of perfection. It is not so; *vixere fortes ante Agamemnona multi* is as true now as when Horace wrote it nearly two thousand years ago. To condemn our ancestors is the vice of imperfect knowledge and of a second-rate education. We can learn from the past quite as much as from the present, and the knowledge which we acquire for ourselves is the better if it be founded upon a historical basis. Pepys is remarkable for the plain and unvarnished accounts which he gives of the facts coming under his notice during the eight years succeeding the Restoration of Charles II. The details of his own illnesses and of those of his wife are as clear as everything else in his Diary. From his accounts we can gather very much more than it would be possible to do had one of the surgeons, or, still worse, one of the physicians, who attended him left us an even more detailed description of his ailments. I think that there is nothing so difficult to determine from contemporary sources as the nature of an illness occurring during the sixteenth, seventeenth, or eighteenth centuries. The humoralist doctrines held sway during this period, as they had done since the beginnings of medicine, and the symptoms of the patient are so overlaid by the theories of his medical attendant that it is often impossible to arrange them in a sufficient sequence to obtain even an approximate diagnosis. The pathology of this date was humoralism tinged with methodism—the doctrine of Themison of Laodicea allied with that of Hippocrates and Galen.

Pepys, like Montaigne, has dissected himself so completely that it is no sacrilege to carry the process farther and lay bare his physical infirmities as thoroughly as he has exhibited to us his many psychical weaknesses, for we shall see that the one depended to some extent upon the other. So much has been written of Pepys that it is only necessary to remind you that he was descended from an old East Anglian family of yeomen farmers, that he was born on Feb. 23rd, 1632-3, and that at the age of twenty-five he married Elizabeth St. Michel, who was then only fifteen. His Diary commences on Jan. 1st, 1659-60, two years after he had been cut successfully for stone at the house of Mrs. Turner in Salisbury-court, Fleet-street, by James Pearse, who was afterwards surgeon to Charles II. and the Duke of York, and Master of the Barber Surgeons' Company in 1675. The tendency to stone was doubtless an inheritance bequeathed to Pepys by his eastern county ancestors, and it appears to have descended to him through the maternal side, for he relates (Nov. 4th, 1680) that his mother was "in greater and greater pain of the stone" when he went to visit her, and (Dec. 21st, 1660) that "my aunt at Brampton has voided a great stone (the first time that ever I heard she was troubled therewith)." He also informs us (Jan. 27th, 1662-3) that his brother John, who had just put on his bachelor's cap at Cambridge, "hath the pain of the stone and makes bloody water with great pain, it beginning just as mine did. I pray God help him." Evelyn, the contemporary diarist, says that the stone removed from Pepys' bladder

was as large as a tennis ball. It weighed, therefore, about two ounces, and I have little doubt that it consisted of uric acid, or of a uric acid nucleus with peripheral layers of ammonium urate, for the recorded symptoms do not in any way point to a mulberry calculus, and it was certainly of renal origin. It may perhaps be found some day, for Pepys treasured it for many years, and in 1684 he paid 24s. for a case in which to keep it. Although the stone was successfully removed on March 26th, 1658—when he was twenty-six years old and had been married for three years—Pepys suffered throughout the period covered by the Diary from certain symptoms in part due to the operation and in part to the formation of fresh stones in his kidney. These renal calculi only once found their way into his bladder, for on March 7th, 1664-5, he passed two after an attack of renal colic. When he died at the age of seventy a nest of seven stones was found in his left kidney. These calculi were, I believe, embedded from the beginning in the renal cortex—a rather unusual situation—and it is to this accident of position that Pepys owes his long life and his comparative immunity from symptoms, for in such cases the secreting substance of the kidney does not suffer, except in the immediate neighbourhood of the stones. He had no increased frequency of micturition, for he would certainly have noted the fact when his nights had been disturbed from such a cause. He had occasional attacks of pain, which were increased by walking, but not by riding. He hardly ever suffered from typical renal colic, but he repeatedly had attacks of pain radiating along his spermatic cord. He never passed blood, and only once in a way did his urine contain phosphates and mucus. These symptoms all point to a cortical stone which would have led him, had he now been living, to have had his kidney opened and the calculi removed, and he would thus have been spared many days of pain and anxiety. The symptoms detailed in his Diary are so explicit that it is possible to ascertain when the calculi were formed or at any rate when his kidney underwent changes in connexion with the presence of the calculi. He had several atypical attacks of renal colic. The first one noted in detail was on Dec. 27th, 1660. Again, on Aug. 1st, 1662, he complains of pain. This attack must have been transient, for on the following day he rode to Rochester, and a few weeks afterwards to Cambridge, on both occasions without producing further symptoms. On Dec. 31st, 1662, he was "very weary and in a little pain from my riding uneasily to-night in the coach." Six years after he had been cut for stone (April 9th, 1664) he says: "I did wake about one o'clock in the morning, a thing I most rarely do, and pissed a little with great pain, continued sleepy, but in a high fever all night, fiery hot, and in some pain." Later in the day he expresses himself as "sick in my stomach and vomited, which I do not use to do." This attack he himself thought was a threatening of ague, but I am more inclined to consider it as marking the formation of a renal calculus, for before the attack became acute he had been complaining of severe pain in his testes from the mere act of crossing his legs. He suffered for many months in 1663 from a pain referred along the course of his spermatic cord, and the least irritation set up an acute or subacute orchitis which (March 26th, 1664) he thinks is "very strange and troublesome to me, though upon the speedy applying of a poultice it goes down again and in two days I am well." The poultice consisted of (Oct. 18th, 1661) "a good handful of bran with half a pint of vinegar and a pint of water, boiled till it be thick, and then a spoonful of honey put to it and so spread in a cloth and laid to it." These attacks of colic were sometimes attended by other symptoms which point to the extension of the inflammatory processes through the perinephric tissue to the posterior surface of the descending colon, where it set up a slight enteritis, leading to constipation from paralysis of the intestinal wall. Thus he gives the following account of such an attack and its cause (June 13th, 1661): "We went toward London in our boat. Palled off our stockings and bathed our legs a great while in the river, which I had not done some years before so to the tavern, where we drank a great deal both wine and beer. So we parted hence and went home with Mr. Falconer, who did give us cherries and good wine. So to boat, and young Poole took us on board the *Charity* and gave us wine there, with which I had full enough, and so to our wherry again and there fell asleep." He reports himself sorrowfully on the following day as "having got a great cold by my playing the fool in the water yesterday, so that I

¹ The meeting was postponed on account of the funeral of Sir William S. Savory, Bart., consulting surgeon to St. Bartholomew's Hospital. No. 3744.

was in great pain and went not to the office at all." He had a worse attack on May 14th, 1664, and it seems to have begun with some cystitis. He describes it very graphically: "Up, full of pain, I believe by cold got yesterday, so to the office where we sat, and after office home to dinner, being in extraordinary pain. After dinner my pain increasing I was forced to go to bed, and by-and-by my pain rose to be as great as ever I remember it was in any fit of the stone both in the lower part of my belly and in my back also. No wind could I break. I took a glyster, but it brought away but little and my height of pain followed it. At last after two hours lying thus in extraordinary anguish, crying and roaring, I know not what, whether it was my great sweating that may do it, but on getting by chance among my other tumblings upon my knees in bed my pain began to grow less and less till in an hour after I was in very little pain, but could break no wind nor make any water, and so continued and slept well all night." Although the acute symptoms subsided and he was able to get about and transact business, it was not until May 19th that he was able to write: "A pretty good stool, and broke wind also." He soon had a fresh attack, and a few days later he sent for Mr. Hollyard, his surgeon, who diagnosed a stone and gave him something to dissolve it. The pain, however, continued, and, as he was not satisfied with the progress he made under Mr. Hollyard's treatment, Dr. Burnett was summoned on July 1st, 1664, "who assures me that I have an ulcer either in the kidneys or bladder, for from my water which he saw yesterday he is sure the sediment is not slime gathered by heat, but is direct pusse. He did write me down some direction what to do for it, but not with the satisfaction I expected. I did give him a piece, with good hopes, however, that his advice will be of use to me." The poor man, however, required but few more fees, for he died in August, 1665 from the plague, which he seems to have caught whilst making a post-mortem examination of one of its victims. If Pepys had but little faith in Dr. Burnett's prescription he trusted implicitly in the utility of a hare's foot to keep off these attacks of colic, and when (Jan. 20th, 1664-65) "Mr. Batten, in Westminster Hall, showed me my mistake that my hare's foot hath not a joint in it It is a strange thing how fancy works, for I no sooner almost handled his foot but my belly began to be loose and to break wind, and whereas I was in some pain yesterday and t'other day, and in fear of more to-day, I became very well and so continue." After such a proof of the efficacy of a hare's foot with a joint in it he got rid of the one he had carried and sent to buy a hare that he might obtain so invaluable a remedy in its proper form.

The attacks of pain from which Pepys suffered were only too often produced by less legitimate causes than cold due to playfulness, and there is no doubt that he suffered directly from the effects of the lateral lithotomy to which he had been subjected, and to the manipulations necessary to remove so large a stone from his bladder. The round shape of the stone, too, would render it difficult to remove, especially with the duckbill forceps and guiders then in use. Johnson's translation of Ambrose Paré's works was first published in 1649, so that we may be certain that the operation was performed after the manner which he describes and with such instruments as are there recommended. Paré says that, after the wound has been made laterally in the perineum and of the bigness of one's thumb, "some one of the silver instruments called by the name of guiders are thrust into the wound as the probe [i.e., the staff] is withdrawn from the bladder. The guiders are then to be thrust and turned up and down in the bladder, and are at length to be staled there by putting in the pin. Then must they be held betwixt the surgeon's fingers. It will also be necessary for the surgeon to put another instrument called the ducks-bill between the two guiders into the capacity of the bladder; hee must thrust it in somewhat violently, and dilate it so thrust in with both his hands, turning it everie way to enlarge the wound as much as shall be sufficient for the admitting the other instruments which are to be put into the bladder: yet it is far better for the patient, if that the wound may with this one instrument bee sufficiently dilated, and the stone pulled forth with the same, without the help of any other." Pepys was sterile, and no doubt exists in my mind that his sterility was due to the left ejaculator having been divided at the time of the operation, whilst the right one was so much bruised by the system of dilatation then employed that it afterwards became occluded. Le Dran states definitely

that injury was often done to seminal ducts in the old operation by the apparatus major, and although in a properly directed lateral incision the deep wound is external to the prostatic portion of the ejaculatory duct, Teevan² records four instances in which after lateral lithotomy there was no emission during sexual intercourse. It is certain that Pepys suffered some permanent injury from his operation, for he had repeated attacks of pain and swelling in his testes, which were independent of the referred pain already described. His testes remained functional for many years, and his prostatic secretion was always sufficiently abundant to prevent him suffering from any lack of emission. The local pain in his testes usually occurred, upon his own confession, when his sexual feelings had been unduly excited, so that it appears clear that the pain was associated with the functional activity of these organs. The mere act of getting drunk he takes but little account of, and it was an event of no infrequent occurrence in the earlier part of his career, for he confesses to sixteen times between April and November, 1661. He considers it troublesome, however, under the following conditions. He and two friends on Nov. 10th, 1661, "sent for two bottles of canary to the Rose, which did do me a great deal of hurt, and did trouble me all night, and indeed came home so out of order that I was loth to say prayers to-night, as I was used ever to do on Sundays, which my wife took notice of, and people of the house, which I am sorry for." Much of Pepys' incontinence must be attributed to the double irritation to which his genito-urinary system was subjected, for on the one hand his kidneys were in a state of constant but subacute irritation owing to the presence of a stone upon the left side, whilst on the other hand his testes, continually secreting, could not give vent to the semen in consequence of the blocked condition of the vasa deferentia. His long spells of sedentary office work and his rather gross habits of life no doubt tended to foster his sexual feelings.

The second great trial in Pepys' life was the trouble he had with his eyesight. He appears to have been ametropic from an early period, but it is clear that he had not used his eyes much during boyhood. He acquired a taste for reading soon after his marriage, and about the time the Diary opens he found that it was necessary for him to improve himself in many branches of education. His work first as Clerk of the Acts, and afterwards as Secretary to the Admiralty, and his post as a Clerk of the Privy Seal, demanded constant perusal of documents, and if we add to this his self-imposed labour of keeping a voluminous diary it is not a matter of any surprise that he soon complains of ocular strain due to such prolonged efforts to converge. He slightly injured his right eye on May 22nd, 1660 by holding his head too much over a gun which he fired off to the honour of the King when he came aboard the fleet which carried him back to England at the Restoration. The injury was soon cured, and it does not appear to have done any permanent injury. It is not until April 25th, 1662, that he complains of his eyesight. He then says: "I was much troubled in my eyes, by reason of the healths I have this day been forced to drink." He began to have a watery eye in the following year, for he says (March 2nd, 1663-4): "Up, my eye mightily out of order with the rheum that is fallen down into it," his left eye being more affected than the right. From this time the complaints about his eyes become more and more frequent, and it is clear that the error of refraction was somewhat greater in his left than in his right eye. He attributed his defective vision at first to cold and to a variety of causes, but he learnt the true cause after a time, and though he suspected it on July 31st, 1663, it is not until June 8th, 1664, that he states "my eyes did ake ready to drop out" after a long evening of writing notes in shorthand. He applied to Ed. Cocker on Oct. 5th, 1664, to ascertain "how I shall do to get some glasse or other to help my eyes by candle-light, and he tells me that he will bring me the helpe he hath within a day or two and show me what to do." Cocker, the altered author of the arithmetic and engraver of letters [1631-1675] whose memory we still commemorate when we say, "According to Cocker," appears to have suggested the use of a pair of green spectacles, which Pepys employed for many years. Increasing age, however, added presbyopia to his hypermetropia, and his sight at last became so bad that after trying many expedients he found himself unable to write up his Diary, which he concludes on May 31st, 1669, with the words: "And thus ends all that I

² Transactions of the Clinical Society, vol. vii., 1874, pp. 179-180.

doubt I shall ever be able to do with my own eyes in the keeping of my Journal, I being not able to do it any longer, having done now so long as to undo my eyes almost every time that I take a pen in my hand." The presbyopia no doubt increased, but he was able to transact the ordinary business of a useful life until May 26th, 1703, when he died.

The minor illnesses of Pepys are neither numerous nor interesting. He suffered from severe attacks of indigestion, usually caused by surfeits, and he records that after a visit to Epsom in July, 1663, which was then a fashionable watering-place, he suffered from a pile the result of the purging produced by a course of the waters, coupled with the additional riding exercise in which he indulged. He was in fear for some time lest the pile should prove a rupture, thereby displaying his lack of even the rudiments of surgical knowledge. He was extremely liable to catarrhal affections, for he was constantly catching cold; on one occasion it was from having his hair cut, on another from leaving off his periwig, and even from sitting without his hat at dinner. The cold was usually cured by simple remedies and left no after-effects, but on one or two occasions he had attacks of tonsillitis. He says (June 12th, 1663) that he was "mightily troubled all night and next morning with the palate of my mouth being down from some cold I took to-day sitting sweating in the playhouse and the wind blowing through the windows upon my head." He suffered, too, from boils, for on Feb. 8th, 1659-60, he records that he "went to bed with my head not well by too much drinking to-day, and I had a boil under my chin which troubled me cruelly." The boil increased in size and there was some stomatitis, for on the following day he "went home and got some alum to my mouth where I have the beginnings of a cancer, and had also a plaster to my boil underneath my chin. The scare of his having a cancer in his mouth subsided after Feb. 10th, when he had been into "London to Mr. Fage about the cancer in my mouth, which begins to grow dangerous, who gave me something for it." Pepys had repeated attacks of nettlerash, which came on annually as soon as the weather began to get cold in the autumn. He cured himself by keeping warm and sweating. He only records one occasion on which he was bled. It was on May 4th, 1662, a very hot Sunday, that he was let blood to the amount of sixteen ounces, when he began to be sick; "but lying upon my back I was presently well again, and did give [Mr. Hollyard, the surgeon] five shillings for his pains." He dined well after the operation and went out walking with his wife after dinner, "my arm being tied up with a black ribbon, our boy waiting on us with his sword, which this day he begins to wear to outdo Sir W. Pen's boy." A few days later he felt constrained to whip this boy with "my whip till I was not able to stir, and then, not being willing to let him go away a conqueror, I took him to task again and so to bed, my arm very weary"; and on several other occasions he administered "salt eel" to the boy, doubtless to neutralise the effect of the sword.

The illnesses of Mrs. Pepys are of less general interest than those of her husband. She was married at the age of fifteen years, so that she had been a wife for four years when the Diary commences. Mr. Wheatley remarks that it is a most curious fact that so methodical and careful a person as Pepys should be in doubt as to the date of his wedding day. Yet so it was, for the register certifies that he was married on Dec. 1st, 1655, in St. Margaret's Church, Westminster, and yet both he and his wife kept the anniversary of their marriage upon Oct. 10th in each year. Mrs. Pepys was childless owing, as I have endeavoured to show, to the sterility of her husband. She had, however, on several occasions a belief that she was pregnant; indeed, the Diary opens with the statement that "my wife gave me hopes of her being with child." Again, on Nov. 6th, 1663, "This morning waking my wife was mighty earnest with me to persuade me that she should prove with child, which, if it be, let it come and welcome." The hope was belied, however. In the following year, on Sept. 27th, 1664, he notes: "So home, where my wife, having (after all her merry discourse of being with child) her months upon her, is gone to bed." The Diary for several years contains an almost uninterrupted account of the pain from which Mrs. Pepys suffered monthly. It was so severe that it quite incapacitated her from doing any household work, and it usually compelled her to keep in bed. She seems to have met the trial bravely, lying up when she was forced to do so, but getting about again as soon as possible. As time wore on the entries about the pain

became fewer and fewer, so that the attacks doubtless became less marked. The pain during the worst period sometimes preceded the flow by a week, but it was more usually coincident with it, and in no case, so far as I can find, did it come on afterwards. It would, therefore, be of that variety to which the term spasmodic (neuralgic or obstructive) dysmenorrhoea is now applied—a condition which, as my friend Dr. Griffith points out to me, is often met with in childless women who have been married young. Mrs. Pepys had a long illness in the winter of 1663. It began, so far as I can ascertain, as an abscess in the vulva, though I think that it is more likely to have been ischio-rectal, pointing, perhaps, a little more anteriorly than is usual. It terminated in a fistula. The surgeon was called in, for Pepys records, on Nov. 16th, 1663, that "in the evening Mr. Hollyard came, and he and I about our great work to look upon my wife's malady, which he did, and it seems her great conflux of humours, heretofore that did use to swell there, did in breaking leave a hollow, which has since gone in further and further, till now it is near three inches deep, but, as God will have it, do not run into the bodyward, but keeps to the outside of the skin, and so he must be forced to cut it open all along, and which my heart I doubt will not serve for me to see done, and yet she will not have anybody else to see it done, no, not even her own mayds, and so I must do it, poor wretch, for her. To-morrow night he is to do it." On the following day, however, "Mr. Hollyard [Thos. Hollier? one of Sergeant-Surgeon Wiseman's wardens in the Barber Surgeons' Company in 1665³] being come to my wife, and there she being in bed, he and I alone to look again upon her [perineum] and there he do find that though it would not be much pain, yet she is so fearful, and the thing will be somewhat painful in the tending, which I shall not be able to look after, but must require a nurse and people about her, so that upon second thoughts he believes that a fomentation will do as well, and though it will be troublesome yet no pain, and what her mayd will be able to do without knowing directly what it is, but only that it may be for the piles. For though it be nothing but what is honest, yet my wife is loth to give occasion to discourse concerning it." The affection ran its usual tedious course; but eventually the fistula healed, and shortly after Christmas Pepys "went after dinner straight on foot to Mr. Hollyard's, and there paid him £3 in full for his physic and work to my wife [about the abscess], but whether it is cured for ever or no I cannot tell, but he says it will never come to anything, though it may be it may ooze now and then a little." I cannot find out when the abscess causing this fistula began, but so far back as 1661 there is an entry that she was suffering from some abdominal trouble, for on May 12th, 1661, "My wife had a troublesome night this night and in great pain, but about the morning her swelling broke, and she was in great ease presently as she useth to be. So I put in a vent (which Dr. Williams [of Eltham?] sent me yesterday) into the hole to keep it open till all the matter be come out, and so I question not that she will soon be well again." It was some time before the abscess healed, for on Midsummer Day Pepys went with his father "and Dr. Williams (who is come to see my wife, whose sore belly is now grown dangerous as she thinks) to the ordinary over against the Exchange, where we dined and had great wrangling with the master of the house when the reckoning was brought to us, he setting down exceeding high everything." There is, however, no further entry in regard to this illness of his wife, though it may have been the starting point of the subsequent fistula.

Mrs. Pepys suffered from earache and from toothache on one or two occasions, but otherwise she appears to have been a tolerably healthy woman. Her earache was cured on June 27th, 1662, by "Mr. Hollard, who had been with my wife to-day, and cured her of her pain in her ear by taking out a most prodigious quantity of hard wax that had hardened itself in the bottom of the ear, of which I am very glad." On Sept. 14th, 1663, she fainted, probably from overfatigue, for setting out from London betimes she came in the evening to Buntingford on the Cambridge road, twenty-nine miles from London, "where my wife by drinking some cold beer, being hot herself, presently after 'lighting, begins to be sick, and became so pale, and I alone with her in a great chamber there, that I thought she would have died, and so in great horror, and having a great

³ The College of Physicians in 1669 bought his house and grounds extending from Warwick-lane to the City walls for £1200 to build a new college in place of the one destroyed by the Great Fire in 1666, which was situated in Amen-corner.

tryall of my true love and passion for her, called the mayds and mistresse of the house, and so with some strong water, and after a little vomit, she came to be pretty well again: and so to bed, and I having put her to bed with great content, I called in my company and supped in the chamber by her, and being very merry in talk, supped and then parted, and I to bed and lay very well." She was well next day, for they went on to Godmanchester [Gumcester] in Huntingdon, and sixty miles from London, where they ate and drank and then to Bampton in Suffolk, which was their journey's end. Once, and once only, she got a black eye—on Dec. 19th, 1664. "Going to bed betimes last night we waked betimes, and from our people's being forced to take the key to go out to light a candle I was very angry, and begun to find fault with my wife for not commanding her servants as she ought. Thereupon, she giving me some cross answer, I did strike her over her left eye such a blow as the poor wretch did cry out, and was in great pain, but yet her spirit was such as to endeavour to bite and scratch me. But I, coying with her, made her leave crying, and sent for butter and parsley, and friends presently one with another, and I up vexed at my heart to think what I had done, for she was forced to lay a poultice or something to her eye all day, and is black, and the people of the house observed it." We have no detailed account of the death of Mrs. Pepys. The fear of becoming blind led to the abrupt termination of the Diary in 1669. Pepys obtained leave of absence from the duties of his office, and set out on a tour through France and Holland, accompanied by his wife. Some months after his return he spoke of his journey as having been "full of health and content," but no sooner had he and his wife returned to London than the latter became seriously ill with a fever. The disease took a fatal turn, and on Nov. 10th, 1669, Elizabeth Pepys died at the early age of twenty-nine years, to the great grief of her husband. Looking to the time of year, to the fact that she had lately returned home from a trip abroad, and to her age, an attack of typhoid fever seems to be the most plausible cause of her premature death, but such a suggestion must be the merest guess. She is buried in St. Olave's Church, Hart-street.

I cannot terminate this short essay without thanking Mr. H. B. Wheatley, the latest and best editor of "Pepys' Diary," and his truest friend, for the kindness with which he has assisted me to certain medical details. In the exercise of a wise discretion, he thought it unnecessary to publish them in a work which, though a classic, is yet read by all classes of Her Majesty's subjects.⁴

THE NEUROTIC ELEMENT IN PULMONARY CONSUMPTION.¹

By THOMAS J. MAYS, A.M., M.D. PHILADELPHIA,
PROFESSOR OF DISEASES OF THE CHEST IN THE PHILADELPHIA POLY-
CLINIC; AND VISITING PHYSICIAN TO THE RUSH HOSPITAL FOR
CONSUMPTION IN PHILADELPHIA.

THAT disorder of the nervous system plays a prominent part in the production of pulmonary consumption I have long been convinced, and in the various papers which I have written on this subject during the last seven or eight years I have made an effort to show the data on which this theory rests. I now call further attention to this interesting subject. I am by no means the first advocate of the nervous theory of pulmonary consumption. As far back as 1842 M. Cheneau² attributed this disease directly to disorder of the pneumogastric nerves, and indirectly to an abnormal condition of the central nervous system. In 1850 Dr. J. C. Holland defined pulmonary consumption as a disordered condition of the nervous system. Dr. Copland regarded tuberculosis and scrofula as being dependent on abnormal conditions of the nervous system and believed that the accompanying disturbances of digestion, assimilation, circulation, and even the local determination of these diseases are traceable to the

state of the nervous influence of these parts. Dr. Laycock, in his clinical lectures on Physiognomical Diagnosis of Disease,³ says that "defective pneumogastric innervation consequent upon a loss of cerebro-spinal power is a very common predisposing and exciting cause of phthisis." Dr. Clifford Allbutt,⁴ in discussing the pathology of a variety of phthisis, states: "The more, however, I study the relations of the disease the more I am satisfied that the lung mischief is also a neurosis—by which I mean that the lesion is one not originating in the local tissues, but in the nervous system." Dr. Clouston, in his recent work, "The Neuroses of Development," says (p. 92) that "facts seem to show that if tuberculosis cannot itself be called a neurosis, it is in most cases dependent for its existence on a trophic neurosis or bears the closest affinity to it." From this it will be seen that this subject has interested some of the most prominent minds in the medical profession during the last fifty years. Indeed, when the richness and fertility of this field of study are surveyed, one is astonished to find how completely it has fallen into abeyance at the present time. It is practically forgotten, yet I believe that a full and thorough examination of its premises will give us proof of the most convincing character that it is the only key to solve the complex etiology of the disease under consideration. At the very outset I would lay down the proposition that any agent or influence which has the power of disordering or of interfering with the integrity of the respiratory nerves in particular, or with the nervous system in general, also has the power of producing pulmonary phthisis and other forms of lung disease. Thus, in a recent canvass of the pathological literature of this subject I found the records of over a hundred cases of phthisis in which the pneumogastric nerves, or the respiratory centres, were compressed or injured or diseased in connexion with syphilis, alcoholism, diphtheria, measles, diabetes, multiple neuritis, locomotor ataxia, bulbar paralysis, tumour of the pons and medulla oblongata, &c.

Phthisis follows in the wake of many nerve poisons. Mercurial tremor and paralysis are well known, but the investigation of Kussmaul develops the fact that the majority of those who suffer from mercurial intoxication, as looking-glass gilders, mercury miners, &c. are very liable to do, also fall victims to pulmonary phthisis. Even the vitality of the offspring of those who suffer from mercurial intoxication is vitiated, for it is said that scrofula, rickets, and pulmonary phthisis are exceedingly prevalent in the children of those who are engaged in mercury manufacture, and that it induces abortion and still-births among female employees. Dr. Bümler cites an interesting instance of mercurial intoxication in a family. A male aged sixty-nine became a glider when thirty-nine years old and worked as such for twenty-five years, when he was compelled to seek other employment on account of serious mercurial poisoning. He was well and worked for twelve years, when he became salivated and suffered from stuttering, tremor, loss of memory, shedding of teeth, &c. He was married three times, and all his wives followed the occupation of gilding. From the first union there were four children, one of whom died from gangrene of both feet, and the other three and the mother died from phthisis. From the second union there were two children, who, with their mother, died from phthisis. From the third union all the children who were born before the mother was employed in gilding were well, while one who was born after this period was a weakling and died from a cause not given, but the mother died from phthisis.

Lead is another metal which has the power of deteriorating the nervous system and of provoking pulmonary phthisis. Statistics show that the disease is from two to three times more prevalent among lead workers in Wales than it is among farmers living in the same locality, or among the general population of England and Wales.

Among the agents which are most potent in the production of phthisis I would place the abuse of alcohol; and I would call the attention to this subject of those who are directly engaged in the study of inebriety. I know that my friend Dr. Crothers has already made some valuable contributions to this question, and I hope to hear of his further experience in this direction. It is well known that this agent exerts a poisonous influence on the nervous system, and especially on the peripheral nerves. Very frequently the nerves do not show any marked changes, but on closer examination evidence of parenchymatous degeneration with more or less

⁴ It is right to say that we have omitted some of the quotations from the Diary, Mr. Pepys' language being occasionally too blunt and outspoken for publication even in a medical journal.—*ED. L.*

⁴ *Ibid.*, vol. ii., p. 613.

interstitial neuritis is discovered. Suppression of the catamenia in women, paralysis of respiration and of deglutition, and disease of the vagi and of the lungs are also observed to be of common occurrence.

Syphilis is another nerve poison which is often the unsuspected cause of pulmonary disease—the typical pathological changes of which are an abundance of interstitial connective tissue proliferation, peri-bronchial induration, diffuse thickening of the lobular parenchyma, syphilitic gummata, and nodular induration or broncho-pneumonia. The poison seems to attack the cranial in preference to the peripheral nerves. That the vagi are frequently implicated is shown by a number of cases among my collection.

Whooping-cough is pre-eminently a specific spasmodic affection of the respiratory nerves. Hufeland, Hoffmann, Wendt, Walshe, and Pridmore ascribe its principal lesion to irritation of the pneumo-gastric nerve. The pulmonary changes of whooping-cough are interesting because they show the direct relationship between the disease of a nerve and that of the organ which it supplies. In all severe cases there is congestion of the pharyngeal, laryngeal, and bronchial mucous membrane and of the lungs, together with dyspnoea and feebleness of the respiratory sounds. There may also be a shade of dulness in some parts of the lungs. Epistaxis, hæmoptysis, emphysema, chronic bronchitis, broncho-pneumonia, and phthisis are frequent complications, especially in the offspring of those who bear a history of chest disease.

Whatever the precise etiology of *influenza* may be, it is essentially a disease of the nervous system. Its morbid anatomy is principally seen in the meninges of the brain, spinal cord, and peripheral nerves. Pulmonary oedema, broncho-pneumonia, capillary bronchitis, and pleurisy are among its common sequelæ. The pulmonary disease was believed by Graves to be due to paralysis of the vagi, and Walshe says this poison seems to exert a special influence on the pneumo-gastric nerve.

Cerebro-spinal meningitis—an affection which chiefly involves the medulla oblongata and its immediate connexions—is nearly always associated with pulmonary derangement. Then there is another group of diseases—the most prominent of which are beri-beri, pellagra, diabetes, and leprosy—in which disease of the nervous system and disease of the pulmonary organ play a prominent rôle.

Epilepsy is also a disease in which the medulla oblongata is involved, and it is in the latter area that we will have to seek an explanation of the ultimate and long-recognised association between this disease and pulmonary disease. Echeverria⁵ states: "I have most closely investigated the relation of pulmonary tuberculosis and epilepsy, and undoubtedly the genesis of tubercles in the lungs is favoured by the lesion in the medulla oblongata proper to epilepsy. I have traced the pulmonary trouble from its inception, and feel convinced that the association is more than a casual coincidence of both morbid conditions." Besides Echeverria, van der Kolk, Jobert de Lambelle, Stuart Cooper, and Rostan reported a number of cases of epilepsy associated with pulmonary disease in which the pons Varolii, medulla oblongata, and vagi were disordered.

Asthma is a spasmodic affection of the pneumo-gastric nerve, and it is therefore of great interest in this connexion to find whether this disorder develops into more serious lung disease or not. Asthmatics are generally supposed to be long-lived, but I do not believe there is much clinical evidence to support this belief. Of course, there are some exceptional cases which undergo spontaneous cure in the later years of life, but in the majority of these sufferers the attacks incline to become continuous, and it is to these my remarks refer. I believe that the tendency in such is a termination in pulmonary phthisis. In support of this Fuller⁶ states that, in spite of the belief that asthma and pulmonary phthisis are antagonistic, many asthmatics die from the latter disease. Williams⁷ shows that in 385 cases of phthisis 7 began with asthma, and states that the tendency of asthmatic parents to have phthisical children is hardly sufficiently recognised. James⁸ asserts that asthma and whooping-cough are likely to predispose to or terminate in phthisis.

Hysteria implicates the respiratory organs in the form of accelerated breathing, dyspnoea, aphonia, laryngeal and pharyngeal paralysis, &c. and has an innate tendency to

develop into pulmonary disease either in the individual or the offspring. Professor Grasset⁹ found that among the parents, brothers and sisters, grandparents, and uncles and aunts of 44 hysterical patients there were 60 who died or suffered from phthisis. Most if not all of these interesting cases furthermore demonstrate that phthisis may follow, or be followed by, alternate with, or evolve from hysteria and other nervous disorders in the same individual. Thus in Cases 2, 26, 27, 30, 42, and 43 phthisis followed hysteria; in Case 4 bronchitis followed catalepsy, and in Case 17 epilepsy preceded phthisis. In Case 28 there was alternation between hysteria, phthisis, and epilepsy; in Case 29 whooping-cough and hysteria preceded phthisis; in Case 31 phthisis existed first, this was displaced by hysteria, after which the patient suffered from sciatica, then from boils, and in the end recovered altogether. In Cases 32 and 33 there was alternation between phthisis and hysteria, and final recovery from both diseases. In Case 34 the patient became phthisical and then suffered from hysteria, during which time the phthisis improved, and in the end she became paraplegic. In Case 35 hysteria came first and then phthisis, after which the hysteria abated and the phthisis progressed. In the end the patient improved. In Case 36 the patient suffered from phthisis and then became hysterical. She recovered from phthisis, but remained hysterical. Case 37 had phthisis first, then hysteria, after which the phthisis improved and disappeared, but the hysteria continued. Case 38 was phthisical first, then became a somnambulist, after which the patient recovered from phthisis. Case 39 had pneumonia, then paraplegia, then phthisis, and finally hysteria. This patient recovered from phthisis. In Case 40 there was phthisis, then hysteria and hemiplegia, after which the phthisis abated. In Case 41 bronchitis appeared first, then convulsions, then phthisis, and finally hysteria. The patient improved in the end. In Case 44 hysteria was entirely displaced by phthisis.

Idiocy has a powerful bearing on this subject. Thus, in 2380 cases of idiocy and imbecility which were admitted into the Royal Albert and Darenth Asylums in England,¹⁰ it was shown that a family history of phthisis existed in 674 of the inmates, or in 28.31 per cent. Dr. Langdon-Down, late physician to the Earlswood Asylum for Idiots, states¹¹ that the statistics of London show that the deaths from phthisis constitute 115 per 1000 of the general mortality. His statistics at Earlswood Asylum indicate that phthisis was the cause of death in 398 per 1000 of the general mortality. His last 100 post-mortem records show that 62 were phthisical, in some of which cases there was no record of disease in the family, and he believes that in these cases phthisis was the sequence of idiocy. "Defective innervation, in all probability, led to malnutrition and predisposed to a tuberculous condition." Dr. Langdon-Down also contributes the histories of twenty families, each of which was burdened with idiocy, and among the parents, sisters, brothers, grandparents, uncles, and aunts of which there were 35 who suffered from phthisis.

The late Dr. Isaac N. Kerlin, superintendent of the Pennsylvania Institute for Feeble-minded Children, in an essay¹² states that if the tables which he presented in that paper were prepared by a special advocate to prove that phthisis is the main factor in the generation of idiocy the effect could not be more startling; but "as they are the result of careful inquiry, without any theory to prove or disprove, I ask for them your respectful judgment." In the table to which he refers he gives the histories of 100 families, in each of which there existed a case of idiocy, and this shows that there were 145 members of these families, only including parents, sisters, brothers, and grandparents, who were afflicted with pulmonary phthisis. In view of the fact that only about 17 per cent. of the general population die of pulmonary phthisis this death-rate is simply enormous. It means that the mortality from this disease is from eight to ten times greater among this unfortunate class than it is among the ordinary population. Moreover, no one is surprised to find that insanity and epilepsy create a special liability to idiocy in the offspring, but it is certainly very startling, especially in the light of its supposed bacillary origin, that phthisis is more powerful in this respect than any other cause which is known to lead to this disease. Thus the statistics of the Royal Albert and Darenth Asylums already alluded to show that among the hereditary causes of 2380 cases of idiocy and

⁸ Pulmonary Phthisis.

imbecility phthisis ranks the highest, having a percentage of 28.31; while insanity, epilepsy, and alcoholism have a percentage of 16.47, 8.69, and 16.38 respectively. Dr. Langdon-Down, in the work already referred to, makes the following pertinent reflections concerning the relationship which exists between phthisis and disorder of the nervous system: "It appears to me that tuberculosis must be accepted as one important cause of idiocy that it impresses special characters thereon, while imparting a strong family likeness to the subjects of this class." It is no less clear to me that idiocy of a non-tuberculous origin leads to tuberculosis. Whether this arises through the influence of the pneumogastric nerve, malassimilation of food, or defective innervation, it cannot but be regarded that the connexion between these two maladies is by no means accidental, and that a due appreciation of this relation is necessary to those who would treat effectively congenital mental lesions.

The clinical association between insanity and pulmonary phthisis has been noticed by many writers, among whom are Van der Kolk, Esquirol, Georget, Burrows, Ellis, McKinnon, Clouston, Boyd, Savage, Norman, Tuke, Laennec, and others. Maudsley says:¹³ "Perhaps I might set it down as a true generalisation that the morbid neurosis, when it is active and gets distinct morbid expression, may manifest itself in four ways: (a) in disorder of sensation—for example, paroxysmal neuralgia; (b) in disorder of motion—for example, epilepsy; (c) in disorder of thought, feeling, and will—mental derangement; and (d) in disorder of nutrition, whereof diabetes is the earlier and phthisis is the later stage." Dr. Blandford states:¹⁴ "I have found, however, that phthisis and insanity do frequently coexist in the same family." Dr. Stearns says:¹⁵ "We often see a consumptive having a child which, instead of developing consumption, develops insanity; and, *vice versa*, an insane person may have children of a phthisical tendency." Dr. Mosher relates an interesting case.¹⁶ A female aged sixteen years was admitted to asylum on Sept. 25th, 1893. She was said to have been insane for eight years, and her attacks were of epileptiform nature, characterised by sudden outbreaks of violence and probably associated with unconsciousness. Heredity was the assigned cause. Eight paternal great uncles and great aunts had died of phthisis, and her paternal grandfather was epileptic in youth and neurotic. During her residence of about six months she had intractable bronchitis and laryngitis with aphonia. Dr. Clouston¹⁷ makes the observations that the death-rate from phthisis among the insane is four times higher than among the general population, and that both diseases are very common in different members of the same family, and that heredity towards phthisis may determine insanity and *vice versa*. The same authority also remarks¹⁸ that the form of insanity which is commonly associated with phthisis is monomania of suspicion and melancholia. Nearly all pure cases of this kind sooner or later die from phthisis. The most marked cases of phthisical insanity are those with a strong hereditary tendency to both insanity and phthisis or to the neuroses. It is surprising how often both diseases occur in different members of the same family. The constitutional weakness which tends to end in insanity (p. 468). Schroeder van der Kolk states¹⁹ that phthisis and insanity frequently coexist or alternate with one another. We often see phthisis occurring in families some members of which are affected with insanity. Dr. Busi, who collected his statistics at the asylum for the insane at Baale, makes the interesting observation²⁰ that in many cases we must regard tuberculosis and insanity as an expression of the same constitutional weakness. In 50 per cent. of his insanity cases there was tuberculous heredity; in 47.2 per cent. there was neuropathic heredity; and in 20 per cent. there was a mixture of the two. On account of the frequency with which both diseases exist in the same families he believes that there is an internal relationship between the tuberculous and psychopathic constitution. Dr. Bianchi describes a pneumonia²¹ which frequently occurs in paralytics, and which differs clinically and anatomically from croupous pneumonia. The temperature is usually low, cough and expectoration are sometimes absent,

the respiratory movements are superficial, weak, and slow, and the affected lung usually remains in a hepatized condition. Frequently there exist larger or smaller gangrenous foci, and nearly always, if the case is of long standing, a puriform infiltration of the alveoli and bronchi. All these manifestations simulate those of pneumonia, which the writer produced in rabbits and dogs by section and compression of the vagi. In a number of paralytics who died of pneumonia he was able to trace a primary degenerative atrophy of the vagi, and hence he believes that these pneumonias are dependent on vagus degeneration. He does not believe, with Traube and Frey, that this pneumonia is engendered by the swallowing of food (Schluck-pneumonia).

This subject is one of vast proportions, and if I had sufficient time I might inquire whether the symptomatic and the therapeutic evidence is not equally as favourable to the neurotic theory of phthisis as that is which comes from the pathological side of this question. Do not the weakness, the easy fatigue, the restless sleep, the extreme nervousness, which is present in many cases, the dyspnea, the hoarseness and aphonia, the thoracic pain, &c., indicate that the principal nature of phthisis is one of nervous exhaustion? And therapeutically is it not true that we get the best results from those measures and agents which prove to be the most efficient in the treatment of nervous diseases? And are not these rest, nutritious food, strychnine, electricity, hypophosphites, cod-liver oil, phenacetin, capicum, quinine, and remedies which appeal to and influence the nervous system?

Philadelphia, Pennsylvania, U.S.A.

TWO CASES OF CARBOLIC ACID COMA INDUCED BY THE APPLICATION OF CARBOLIC COMPRESSES TO THE SKIN.

BY R. CLEMENT LUCAS, B.S. LOND., F.R.C.S.,

SURGEON TO GUY'S HOSPITAL;

AND

W. ARBUTHNOT LANE, M.S. LOND., F.R.C.S.,

ASSISTANT SURGEON TO GUY'S HOSPITAL.

THE following cases, which have recently been under our care in Guy's Hospital, appear to us to be of such rarity and importance as to justify their early publication, and we publish them chiefly with the object of rendering our experience of service to others. Since it has been shown that the disinfection of the skin in the immediate neighbourhood of an operation is of the utmost importance before commencing to wound the integument, it has long been our practice to apply to it a compress of lint soaked in a 5 per cent. solution of carbolic acid in water for a variable time before an operation is undertaken. Many hundreds of patients must have been thus prepared in the wards of Guy's Hospital, but with the exception of the two cases we are about to relate we know of no cases that have presented symptoms of such serious import. Headaches and sickness, together with carbolic acid, may have been occasionally noticed, and the earlier symptoms may have been confused with those attributable to an anæsthetic; but in these two patients complete coma lasting for several hours was induced before any operation was commenced, and in the first case grave symptoms occurred on two occasions. These symptoms, if they developed for the first time during or immediately after an operation, might cause the surgeon the greatest anxiety, especially as the cause might not be immediately obvious. It is not difficult to imagine many circumstances under which the sudden onset of this condition of coma might induce the operator to take steps of an unnecessary or even damaging nature to the patient. Anything more distressing could scarcely be conceived than for a case such as these to occur in private practice. The nurse might have been instructed to apply the compress over-night and the surgeon might be called to find his patient in a state of coma from which it might be impossible to rouse him for four or even eight hours. Happily this peculiar susceptibility to the phenol poison must be of very rare occurrence, or it would have been noticed earlier among the large number of patients

who have been treated in a similar way. The following are the cases.

CASE 1.—A boy aged fifteen years was admitted into Job Ward, Guy's Hospital, on Aug. 27th, 1894, under the care of Mr. R. Clement Lucas. In 1891, during convalescence from typhoid fever, he suffered acute pain in both legs and in the right hip. Abscesses formed about the right hip, and ankylosis of this joint followed. Considerable thickening of both femora near the knees was also noticed. He had on two previous occasions, during 1892 and 1893, been under Mr. Lucas's care for the treatment of sinuses connected with diseased bone. On this occasion there were three small sinuses remaining in the right thigh and thickening of both femora. At noon a carbolic compress was applied over the right thigh to prepare him for an operation in the evening. The operation, however, had to be postponed. In the evening he was very sick, and at 2.30 A.M. on the following morning the nurse's attention was drawn to him by hearing his breathing stertorous, and on going to him found that he was insensible. She immediately sent for the house surgeon, Mr. G. Lawrence, who found him lying on his back with his head turned to the left. When first discovered he was found to have vomited on the pillow. His pulse could not be counted at the wrist, but by the heart it was 200. The pupils were moderately small, reacting slightly to light. His breathing was very stertorous and complicated by much mucus in the throat. He was in a profuse perspiration all over. There was no corneal reflex. His limbs dropped loosely when lifted, but sharp stimuli excited slight movements, especially in the arms. He had not passed urine. After a time he began to moan with each expiration, and continued steadily to do so, and seemed to get gradually lower. Brandy and strychnine were given at once without producing much effect. Hot-water bottles were put around him. He gradually came round to a state of semi-perception of stimuli, moving his arms slowly and aimlessly and making less noise. He appeared unable to clear his throat of mucus, and the cry at the end of expiration seemed to indicate pain. Later he became more quiet, and his pulse was counted at 150. Pinching his limbs excited cries of pain, but not much movement. The pulse remained very feeble, and cold perspiration continued. The breathing was quiet, but rattling. He was apparently asleep, but pinching did not rouse him. At 10 A.M. he was still comatose and could not be roused to answer questions. He was sick and weak. The pulse was 120 and feeble. About half an hour later he regained partial consciousness, but was heavy and stupid all day. The urine passed was found to be very dark in colour from absorption of carbolic acid. On Aug. 29th the patient still felt sick, and vomiting occurred now and again. He was very thirsty. The pulse was 126 and the temperature 101.8° F. His breathing was quiet. In the evening his temperature rose to 103.4°. On Aug. 30th his temperature at 10 A.M. had fallen to 100.8°. Sickness occurred occasionally. On Aug. 31st the sickness ceased. The patient had a hectic flush on each cheek. He felt much better. The temperature was 99.6°. On Sept. 1st he was feeling quite well. On Sept. 3rd it was again arranged to operate and a short time before some 5 per cent. solution of carbolic acid was applied on lint to the thigh. Soon he was noticed to be sick and shivering, and his skin was bathed in perspiration. His temperature was only 95° and his pulse scarcely perceptible. He was stupid and answered questions with difficulty. The operation was in consequence postponed, the compresses removed, and the skin of the thigh thoroughly washed with warm water. Subsequently for two days his urine was dark from the absorption of carbolic acid.

CASE 2.¹—A boy aged six and a half years was admitted under the care of Mr. Lane on Jan. 30th, 1895, suffering from a swelling in the right iliac fossa, which it was proposed to explore on the following day. The dresser applied to the skin over and in the vicinity of the mass a compress moistened with carbolic lotion (1 in 20). This was done at 12.20 P.M. At 1.30 P.M., after it had been in position for an hour and ten minutes, the sister of the ward heard the child groaning, and on examining him was so alarmed that she sent at once for the house surgeon. On his arrival a few minutes later he found the boy pale, collapsed, and comatose. There was marked dyspnoea, with convulsive twitchings of the eyelids and limbs. The pulse was 130, feeble, and intermittent; the respiration was 72,

and the temperature 97° F. Ether and atropine were injected hypodermically and brandy given by the rectum. The patient was wrapped in blankets and hot bottles were applied. The interrupted current was also used. After this his condition became somewhat less alarming, his pulse improving in character and his respiration being less laboured. At 3 P.M. the pulse was 150 and the respiration 72. The eyelids still twitched and the tetanic contractions of the muscles of the forearm and hand continued. The pupils were dilated and reacted slightly to light, the face was flushed, the lips less livid, and the body was covered by a profuse perspiration. The skin at this time showed no sign of having been irritated by the carbolic lotion. At 4.30 P.M. the pulse was 146, much stronger, and the respiration 72. The twitching of the eyelids had ceased, together with the difficulty of breathing, though the respirations were still abnormally shallow and rapid. The patient had been perspiring freely since the last observation. At 6 P.M. the condition of the pulse and respiration did not differ from that observed at 4.30 P.M. The patient was still perspiring, and he screamed a good deal and appeared to be commencing to regain consciousness. He vomited some dark fluid, which appeared to be imperfectly digested beef-tea, after which he seemed much relieved. At 7.30 P.M. the patient was quite conscious and talked quite rationally. The pulse was 120, full and strong, the respiration 32, and the temperature 98.4°. He had vomited several times since the last observation. He passed some urine which was very dark green in colour, distinctly acid, having a slight deposit of urates, but containing neither albumen nor sugar. It gave the ordinary reactions for carbolic acid and its products in urine. He continued to vomit at intervals until the afternoon of the next day. He passed some more urine in the morning of the same character as the last. The respirations fell in frequency to twenty-four during the night, his pulse not changing. On Feb. 1st, at 2 A.M., his temperature was 99.2°, and at 6 A.M. it was 98.6°. Though on Feb. 2nd the child seemed fairly comfortable except for a little exhaustion, possibly consequent on the vomiting, yet it was several days before he was restored to his original condition of health. It would seem probable that, but for the prompt action of the house surgeon, Mr. D. M. Beddoe, the child's condition might have become much more serious than it did.

Remarks by Mr. LUCAS.—It will be observed that the earlier symptoms in these cases (best studied, perhaps, in the second attack of the first patient) are those of extreme collapse, accompanied by a low temperature, extremely rapid, feeble pulse, vomiting, and profuse perspiration. Then the patient passes into coma, with stertorous breathing and insensitive corneal reflex. The pulse may become so feeble as not to be felt at the wrist and so rapid as almost to defy an attempt to count it. In the first case taken at the heart it was counted as 200, and in the second patient when at the worst 150. The rapid pulse and feeble heart's action seem to suggest the direction in which the greatest danger lies. The stertor was in both cases a most striking feature, accompanied by clogging of mucus about the throat. Although the coma was absolute as regards the intellectual faculties, it will be observed that in both cases the pupils were found to react to light. In the first patient the pupils were described as moderately contracted; in the second case observation does not seem to have been made until after the subcutaneous injection of atropine, and they were probably dilated by that drug, though still not paralysed to light. Twitchings of the eyelids and slight tetanic contractions of the hands and arms suggested the appearance not infrequently noted in uræmia, and as the urine appears to be temporarily suppressed these symptoms may be referable primarily to renal derangement. As the patient improves the pulse becomes stronger and the stertorous respiration is relieved by moans and cries. The time which the coma may last is again remarkable. In the first case, although all dressings were removed, the patient remained unconscious for eight hours, and the second patient was insensible for four hours. Vomiting and carbouluria may continue for two or three days after recovery of consciousness. In one case, after reaction from the collapse, the temperature rose as high as 103.4° F., but in the case which lasted the shorter time the reaction only reached 99.2°. As regards treatment the first indication is to thoroughly wash the skin to which the carbolic lotion has been applied, so as to prevent any further absorption, and next to treat the collapse. Hot bottles and warm blankets to the surface, with warm brandy enemata and the subcutaneous injection

¹ The notes of this case were compiled by the child's dresser, Mr. J. T. Roberts, who watched the child constantly for many hours.

of ether, are the means best adapted for this purpose. Strychnine or atropine may also perhaps be of service. In spite of the alarming and persistent nature of the symptoms our experience would lead us to give a favourable prognosis if the cause were recognised sufficiently early and means at once taken to prevent any further absorption. That the absorption was by the skin in both cases there can be no shadow of doubt, for in the first case there were only three small sinuses open, and in the second the skin was unbroken.

NOTES OF A SEVERE AND PERSISTENT CASE OF HICCOUGH.

By J. P. WIGHTMAN, M.R.C.S. ENG., L.R.C.P. LOND.

I HAVE thought it worth while to bring forward the notes of this case on account of its comparative rarity, and also because text-books and even books of reference are silent, or tell one little, as regards the treatment of the complaint. In the following case uræmia, the passage of a gall-stone, or implication of the diaphragm, inflammatory or otherwise, could be excluded. Nor was there any evidence of implication of the phrenic nerves in the thorax or neck. There were no signs of intra-thoracic or intra-abdominal growth or aneurysm. There was no evidence of intra-cranial mischief. There was, however, a history that made one suspicious that the attack might have been neurotic. About six years ago the patient had much mental worry and disappointment. Since then, with fairly long intervals between, he has had what he called "fainting" attacks. His description of them was that, whilst thinking deeply on any subject, another intruded itself, the two getting mixed up together; then something seemed to form in the epigastrium and gradually rose up towards his head, whereupon he lost consciousness. Bystanders who had seen him in an attack said that he turned pale, slid down off his chair on to the floor, his eyes being widely open; his hands were flexed at the wrists, there was no struggling, and the attacks lasted a few minutes. Small scars, due to cuts on the head and chin, were visible, these being due to injuries received by falling during an attack some years ago. He never bit his tongue or passed urine or fæces. There had been two previous attacks of hicough, each attack lasting a few hours. Together with these notes it is worth while, I think, to include short notes of a few other cases of hicough—especially of two, with the results of the respective post-mortem examinations.

About twelve years ago a letter of inquiry by Dr. James Weaver as to the treatment of this complaint was published in *THE LANCET*.¹ The patient was a man aged sixty-eight. On and off the hicough had persisted for seven months, alternating with attacks of bronchitis. All known treatments had been tried and had failed to cure. The patient died, the fatal illness presenting the character of broncho-pneumonia complicated by hicough. Often for days he had obtained no sleep owing to the hicough. Morphia, chloral, and bromides produced frenzy. The only treatment that palliated the complaint was inhalation of chloroform. The necropsy showed large masses of scirrhus at the root of the left lung, in which were embedded the pulmonary artery and vein. On the upper and left side of the diaphragm was a patch, rough and hard, covered with millet-seed-looking bodies. Amongst the answers that Dr. Weaver's inquiry called forth a case was mentioned where hicough occurred as the first symptom of cancer of the stomach in an old man.² Another case was the subject of aortic valvular disease. Chloroform inhalation was mentioned as curing in early stages.³ The notes of another fatal case were published soon afterwards⁴—viz., that of a man aged forty-four. At the post-mortem examination the pericardium was found to be completely adherent to the heart, which was very small. The right lung was studded all over with hard caseous nodules about the size of peas. At the root of each lung, surrounding the bronchus, were large caseous masses. The probable cause of the hicough was implication of the phrenic nerve or vagus. In this case there was complete absence of the physical signs and symptoms that

would tend to reveal the true nature of the case. In another medical journal⁵ reference is made to a further fatal case; no mention is made of a necropsy. In the same publication⁶ reference is made to a woman aged forty-eight. She had been ill for nine months, suffering from extensive pulsation of the aorta, just below the diaphragm, with emesis and general wasting and diminution in power over the left side. The duration of the hicough is not stated. There are also notes of a case of long-continued hicough.⁷ Its duration was twenty-two weeks, though it did not occur during sleep. Improvement began when pills containing iodoform, extract of cannabis indica, and extract of hemlock were given. Tobacco-smoking and alcoholism are also mentioned elsewhere as being the causes occasionally of severe hicough. In *THE LANCET*⁸ Mr. D. Ferguson of Camden Town published a case of prolonged hicough which resisted all treatments until the subcutaneous injection of morphia and atropine was tried, but after which most alarming symptoms manifested themselves, the worst feature in this case being the inability to take food. I will now proceed to the description of the case which is the subject of this paper.

A man aged fifty-eight first came under my notice on March 18th, 1895. He was a total abstainer, but was in the habit of drinking much tea. He had smoked half an ounce of tobacco per diem of late years and was a very small eater. He stated that he had had constant hicough for forty-eight hours. I prescribed him chloral hydrate, gr. xv., and bromide of potassium, gr. xxx., in a draught at bedtime. On the following day he had five hours' sleep, but the hicough recommenced on his waking. I now gave him chloral hydrate, gr. xxx., bromide of potassium, dr. i., with water to two ounces—half at 3 P.M. and the remainder at bedtime. Pressure over the region of the phrenics at the lower and front part of the neck stopped the hicough for a short time. On the 20th he had a quiet night on the whole. The hicough was worse in the morning. There were violent and frequent contractions of the diaphragm, frequently one hicough being represented by five or six consecutive contractions. The hicough occurred eight to ten times in a minute, sometimes more frequently. The pulse was good and regular, but the tension was high and the arteries were thickened. The temperature was normal. The face was flushed. There was no vomiting. Pressure over the phrenics had no effect. The urine was of sp. gr. 1025 and contained no albumen or sugar, a normal quantity being passed. A blister three inches square was ordered to be applied over the region of the diaphragm in front, as well as ice to the nape of the neck and spine. At 8.30 P.M. the hicough was still violent. The temperature was 100° F. and the pulse 64. The following was prescribed: chloral hydrate, gr. xx., bromide of potassium, gr. xx., to be taken immediately. As soon as the effect of the draught had subsided he was to have spirit of camphor, min. lxxx., tincture of belladonna, dr. i., bromide of potassium, gr. lxxx., with water to four ounces, one ounce to be taken every three hours. On the 21st the hicough was still severe and frequent. He had had a bad night, talking in his sleep which had been much interrupted. The blister had risen well. The temperature was normal and the pulse 64. The lungs were natural, as was also the urine. Regurgitation of sour fluid into the mouth took place during the early part of the afternoon; after this he had two hours' sleep. The hicough was now violent. He was ordered sulphate of zinc, gr. xxx., with water to one ounce, to be taken immediately. At 10.30 P.M. the emetic caused retching only. One-fifth of a grain of morphia was injected hypodermically. On the 22nd he went to sleep after an injection of morphia. Stertorous breathing came on, which alarmed his attendants for a time. He slept nearly all night, but hicough persisted throughout. The pulse was regular; the specific gravity of the urine was 1023. He was prescribed musk powders (six grains) every two hours. At 5 P.M. the hicough persisted quite as frequently as before and was of a similar character. The patient complained of sore-throat at times. Nitrite of amyl inhalation was tried, but had no effect. He now took nourishment well and was passing a full quantity of urine, which contained ten grains of urea to one ounce, but no sugar. At 9 P.M. he was rather exhausted. A hypodermic injection of one-seventh of a grain of morphia was given. On the 23rd he had no sleep until 5 A.M. He was light-headed and talked a good deal during the night. He was now taking milk or

⁸ THE LANCET, Feb. 16th, 1895.

weak tea with light food and half an ounce of brandy every four hours. The pulse was 56 and regular. The face and the conjunctivæ were somewhat jaundiced. There was no headache or vomiting. The examination of the chest proved to be negative, except that rhonchus and sibilus were heard at the left base behind. There was some cough with expectoration. The heart's apex beat was situated at the fifth interval, half an inch inside the nipple line. There was no distension of the abdomen and no perceptible enlargement of the liver; liver dulness appeared to be natural. Stomach resonance was normal. The urine was rather dark, but did not contain bile pigment. The faeces were hard and of a dark colour. At 9.30 P.M. he was given bromidia, dr. i., with water to one ounce, to be taken at once as a draught. On the 24th he had not much sleep. The pulse was 62. He had some cough. The hiccough had been very severe during the previous night, worse than before; he had, however, taken food well. Dr. Walter R. Jordan of Birmingham kindly saw the patient in consultation with me, and the following medicine was tried: ammoniated tincture of valerian, dr. vi.; bromide of potassium, dr. ii.; chloral hydrate, gr. xc.; with water to six ounces; one ounce to be taken every four hours. On the 25th he had five hours' sleep, during which time the hiccough stopped, but recommenced on his waking. He had a good breakfast. At 6.30 P.M. I was sent for because the patient was "not himself," delirious and drowsy, these symptoms apparently coming on suddenly after a copious motion at midday. The patient was now very drowsy and talking nonsense; his face was flushed; he could, however, be roused, and then complained of severe girdle pain at the epigastric level. The pulse was steady, the tension being low. The hiccough was severe. He also complained of a tingling sensation over the chest and arms. The medicine was ordered to be stopped and hot coffee to be given. At 10 P.M. he was much less drowsy. The skin was hot, the temperature being normal. The epigastric pain had gone. On the 26th, about midnight, he tried to get out of bed. Another dose of bromide and chloral was given, although contrary to orders. He slept for six hours without hiccough. In the morning the patient seemed to be much better. The pulse was steady and the bowels were opened. He had a good breakfast. Hiccough was still frequent. The following was prescribed: chloral hydrate, gr. x., bromide of potassium, gr. xv., and water to one ounce, to be taken at 3 P.M. At 9.30 P.M., after the draught, he slept for five hours. He took food well, but the cough was troublesome. The pulse was good. The urine was of sp. gr. 1015 and contained no albumen. On the 27th he had a fair night. For the first time since the onset of the illness, eleven days previously, he was free from hiccough whilst awake. The pulse was rather weak, but regular and not hurried. He woke up suddenly in the night, startled, and coughed much for a short time. Brandy was increased to one ounce every four hours. Expectorant medicine was administered. At 9.30 P.M. the hiccough had returned, being frequent but not very severe; otherwise the patient's condition was satisfactory, though he felt weak. The pulse was stronger. The draught as given on March 26th was repeated. On the 28th the patient took the draught at midnight and slept well. His condition was quite satisfactory. There was no hiccough, but the voice was husky. The pulse was good. At 9.30 P.M. he had been without hiccough all day. The voice was still husky and the throat sore. There was some precordial pain during the evening, with throbbing of the heart. The pulse-rate was 52. Examination of the fauces gave a negative result. On the 29th he had had a good night's rest without the draught. There was no hiccough for twenty-four hours. He felt very weak, but the pulse was good. On his eyes being examined the fundi were found to be normal, as were also the optic discs, but there was abnormal refraction (both eyes - 6D). On the 30th there was no hiccough. The patient was convalescent and was allowed to get up for half an hour. On the 31st his condition was satisfactory, though he felt very much shaken. He was dressed and came downstairs. The voice was only slightly husky.

Remarks.—In this case the history of previous attacks of hiccough and also of the "fainting" attacks, which appear to have been of an epileptiform character, is interesting. In the absence of any obvious cause—e.g., uræmia, new growth, &c.—one may look upon the attack as a form of epileptic "nerve storm," though, of course, it is possible that there had been some local pathological condition. The pulse, even at the height of the attack, was never more than 64 per

minute and usually not over 56. The best sign all through the attack was that the patient took his food well. The severity of the hiccough may be understood by stating that frequently the spasms so shook the body that the bed, a heavy one, shook also. No other muscle besides the diaphragm was implicated. The urgent symptoms on the night of March 21st, which made his relatives think that he was dying, were not so very alarming as far as I can make out. Some collection of mucus probably caused the noisy breathing, which seems to have awakened the patient himself, for he woke up suddenly and asked what was the matter. The bad symptoms on March 25th may, I think, be put down to the doses of chloral that he had taken. There is no family history of paroxysmal neuroses.

Leeds-road, Rawdon.

THE TREATMENT OF FRACTURES.

By D. M. BEDDOE, F.R.C.S. Eng.

THE recent developments in the knowledge of wound infection, and the resulting increase in the means of preventing such, have led medical men to actively interfere for the relief of patients in regions where, without that means, they dare not trespass. In treating any affection the surgeon, now confident in his aseptic precautions, instead of doubtfully asking himself whether he dare make an incision or not, inquires rather what benefit to his patient will accrue therefrom. This being so, it is curious that, with the exception of one or two isolated cases, attempts have not been made to deal more actively with fractured bones than by placing them in splints. Perchance this is due to a want of knowledge of the after-history of persons who have sustained an injury of this kind. Not long ago, in order to satisfy my mind upon the efficacy of the usual splint treatment of fractures, I made an inquiry into the subsequent history of a number of persons who had sustained such an injury, taking up for this purpose two particular lesions of the lower extremity—viz., simple fracture of the shaft of the femur and Pott's fracture; and I fear that the results will show that we are no whit better off now than when John Bell said many years ago "that an effectual method of securing oblique fractures in the bones of the extremities, and especially of the thigh bone, is perhaps one of the greatest desiderata of modern surgery, and frequent lameness shows that we are still deficient in this branch of practice." In this investigation I have confined myself almost exclusively to those fractures occurring in working men between the ages of thirty and sixty, as it is for them more particularly that the possession of a firm, stable limb is of such vital importance, and I wish it to be distinctly understood that no selection was employed in their collection. The various details concerning these cases, together with the ascertained results, are given in the annexed tables.

Thus, as regards the 16 cases of fractured femur, the following lamentable results occur: 3 are unable to follow any occupation; 1 is able to do but a few light odd jobs; 4 cannot work nearly as well as before, and their wage-earning power has much decreased; 1 can do fairly heavy work, but is unable to climb ladders when carrying weights owing to a stiff knee (he could not do any work for six months); 1 is able to do fairly heavy work, but is out of employment because he could not do any work for seven months; 4 only can do their work as well as before, and of these one was unable to work for five months and another for three. Of the Pott's fractures, 3 have been able to do but very little work since; 5 are able to do their work only at the cost of some pain and considerable inconvenience (one of these was five months before he could do any work at all); 1 cannot walk any distance on account of the pain in his ankle and subastragoloid joints; the remaining 4 are able to do their work satisfactorily, but occasionally suffer from pain in the ankle. When one sees results such as these following treatment, where for broken thigh the patients remained in hospital in no case for less than six weeks, and under all the advantages that skill and appliances can give, it is surely suggestive that there is something radically wrong in our methods of procedure, and a consideration of the conditions of a recent fracture, and the agencies to be overcome in its proper treatment support this contention; thus, in the case of a

TABLE I.—*Pott's Fractures.*

No.	Occupation.	Age.	Date of fracture.	Time in hospital.	Present condition.	Condition as regards work.
1	Carman	30	1893	14 days	Depression at seat of fracture.	Ankle was very weak for some time; still has pain after a hard day's work.
2	Labourer	32	1893	14 days	Distinct depression 1½ in. above external malleolus, the displacement of fragments not having been reduced.	Has continual pain in ankle and subastragloid joints; impossible to do anything but the lightest work, and that with considerable pain.
3	Bricklayer's labourer	49	1893	A few days	Slight depression at seat of fracture; some eversion still.	Quite unable to do any work for five months; has been able to do but very little since from pain in ankle and subastragloid joints.
4	Accountant	58	1893	6 days	Depression at seat of fracture.	Unable to walk any distance from pain in ankle and subastragloid joints.
5	Stickmaker	64	1893	14 days	No displacement, but a little thickening of bone at seat of fracture.	Has pain on standing for some time.
6	Labourer	53	1891	A month	Movement at ankle-joint somewhat limited.	Returned to work in two months; has suffered much pain at intervals; ankle still feels very weak.
7	Leather-dresser	27	1891	3 days	Slight depression at seat of fracture.	Patient does his work, but suffers great inconvenience when standing on it for long.
8	Dock labourer	35	1893	A few days	No displacement.	Pain on change of weather only.
9	Labourer	31	1891	Two days	—	Can work as well as ever; very occasional pain only.
10	Waterside labourer	32	1892	Five days	Slight displacement; no deformity.	Has not been able to do much work since on account of pain in ankle.
11	Constable	29	1893	A few days	—	Can do his work all right; has occasional pain only.
12	Porter	38	March, 1894	Seven days	A slight rim at seat of fracture.	Has a good deal of pain in his foot occasionally, and is able to follow his employment, but with some discomfort.
13	Engine man	43	Feb., 1894	A few days	No displacement.	Can now work as well as before, but he had a good deal of pain for some months after the accident.

TABLE II.—*Fractured Shaft of the Femur.*

No.	Occupation.	Age.*	Date of fracture.	Seat of fracture.	Time in hospital.	Condition on discharge.	Present condition.	Capacity for work.
1	Labourer	50	June, 1892	Junction of middle and lower thirds	Six weeks	Satisfactory; ¼ in. short	Pain and weakness at seat of fracture; pain and stiffness in knee; no obvious deformity.	Is unable to follow his regular employment; can do odd jobs only; earns but very little.
2	Carman	36	June, 1890	Middle third	Eleven weeks	Apparently satisfactory	Lame; pain in knee and hip; knees swell after walking; bowing of femur.	Cannot work nearly so well as before accident; was nine months before he could do any work at all.
3	Boot welter	43	1892	Middle and upper thirds	Seven weeks	Apparently satisfactory	Lame; pain in thigh.	Cannot do his work so well; was eighteen months before he could work, and then could not stand for any length of time.
4	Labourer	58	1890	Fracture in two places	Four months	2 in. short	Pain and weakness in limb at seat of fracture and in knee-joint.	Has done no work since.
5	Riverside labourer	40	1893	Upper and middle thirds	Six weeks	¾ in. short	Lame; occasional pain in thigh.	Is not able to work nearly as well as before; his wage-earning power has much diminished; was six months before he could work at all.
6	Fitter's labourer	55	1893	Upper third	Seven weeks	Some little deformity	Lame; pain and insecurity in limb; limb occasionally helpless, bowing outwards.	Is not able to work nearly as well as before; was four months before he did anything.
7	Blacksmith	40	1894	Above centre	Nine weeks	—	2½ in. short; increasing pain in knee and hip; can only hobble with a stick.	Unable to follow any employment.
8	Porter	38	1890	Upper third	—	—	1½ in. short; pain in the thigh, discomfort in knee and hip; cannot bear his weight upon his leg.	Unable to follow any occupation.
9	Engine driver	53	1893	Lower third	Six weeks	1 in. short; adhesion in knee broken down in three months	No deformity; slight pain in ankle on exertion; foot rotated inwards slightly.	Can perform heavy work, but is out of employment consequent upon his being incapacitated for seven months.
10	Labourer	32	1892	Lower third	Six weeks	½ in. short	No pain; not lame; foot turns out a little.	Can work well.
11	Carman	59	1892	Middle and upper thirds	Seven weeks	1 in. short	No pain; limps a little.	—
12	Drayman	47	1890	Lower and middle thirds	Eight weeks	1½ in. short	Good firm limb, but cannot flex knee to full extent.	Can work satisfactorily, but cannot carry weight uphill; could not work for six months.
13	Carman	37	1899	Lower and middle thirds	Six weeks	½ in. short	No lameness and no deformity.	Can do his work as well as before.
14	Labourer	29	1891	Middle third	Six weeks	½ in. short	No lameness and no deformity.	Can work well, but could not for nine weeks.
15	Watchman	42	1890	Middle third	Seven weeks	—	No lameness, no deformity, and no pain.	Can work well, but was unable to for three months.
16	Drayman	49	1893	Upper and middle thirds	Nine weeks	¾ in. short	No lameness, no deformity, and no pain.	Can work as well as before.

* Age refers to age at time of fracture.

recent fracture of the femur, which in an adult is almost invariably oblique,¹ we may take it that there is almost always some overlapping of the bones, and from the great eversion of the foot, which is almost always constant, there must also be some rotation of the fragments. To take this overlapping first. It is generally said that the cause of this position of the fragments is due, with the exception, perhaps, of the fracturing force, to active muscular contraction; but this overlapping is present, and often almost as difficult to reduce when the muscles are fully relaxed under the influence of an anæsthetic as without, and it seems reasonable to suppose, as Mr. Arbuthnot Lane contends,² that the shortening from a broken bone is due to the blood extravasation and effusion into and beneath the soft tissues around the fracture, which bulging out the skin and tissues causes the limb to undergo in proportion a compensatory shortening and resists reduction. Of the truth of this observation I am perfectly satisfied, for I have seen several cases where this difficulty of reduction could be explained in no other way. To give an example. Not long since I saw two cases of compound fracture of the leg, in one of which there was a large ragged wound through which the effused blood found a ready exit; whilst in the other there was a much smaller hole partly blocked by the fragment. The former was easily reduced, but the latter, even under an anæsthetic, taxed the full powers of the surgeon to satisfactorily reduce it, although the tendo Achillis had also been divided. I have observed also from records of cases that the amount of shortening is often proportionate to the amount of effusion. It is clear, therefore, that to put up an overlapping fracture in an unyielding envelope such as plaster-of-Paris, as is so often done, simply retains the fragments in their abnormal relation, in which undesirable position they become permanently fixed. As regards this, the method of continuous extension is infinitely preferable; but even here it seems, to judge by the invariable shortening, that the bones unite sufficiently firmly to prevent full apposition before the counteracting effusion has ceased to act. As Hamilton³ says: "When the ends have once become completely displaced no means have yet been devised by which an overlapping and consequent shortening of the bone can generally be prevented." Of fifty cases of fractured femur Mr. Holthouse⁴ found that 90 per cent. had shortening varying from $\frac{1}{2}$ in. to $3\frac{1}{2}$ in. The application of the various means of extension also is not without grave inconveniences—chafing of the skin, blisters, intractable ulcers, and stiff joints often resulting. As Velpeau says, most of these contrivances fail to obviate the shortening, and produce eschars, ankylosis, or troublesome arrests of the circulation.

With reference to the second displacement—namely, that of rotation—it is curious what little attention has been paid to it. It seems sufficient to the minds of most surgeons to correct the extreme eversion only without any definite rule for its more accurate position. For instance, if the fractured femur be treated by means of a long Liston or Desault, the foot is at a right angle to the bed, whereas in a Hodgen the foot may lie in any position from a right angle to as much, perhaps, as 65° . Now, as has been pointed out by Mr. Arbuthnot Lane,⁵ the lower extremity in a position of rest has the foot at an angle of about 45° , the limb rotating outwards from the hip-joint; it is clear, therefore, that if the foot be at a right angle the ends of the fragments do not correspond, but the lower one is twisted inwards to the upper, whilst if the foot be rotated out to an extent exceeding about 45° there is a twist outwards of the lower fragment. I have seen instances of these conditions both in living subjects and in museum specimens of old fractures. Concerning the importance to be attached to a certain amount of overlapping and rotation it may be argued by some that so long as the bones are firmly united a slight amount of shortening is a matter of no moment. Thus Erichsen states "that a slight diminution in the length of a limb is of no consequence, the pelvis remedying this"; and Hamilton⁶ says "that in shortening over two-fifths of an inch either they limp, or they have lifted the heel of the shoe, or, in short, the limping is only concealed by a lateral deviation of the spine." What effect in the long run this deviation has one does not exactly know; but I have met with several instances where the patients have complained of pain and weariness in the back after doing work, which they

say they did not experience previously to the occurrence of the fracture. This is suggestive that this compensation on the part of the spine is not altogether to the advantage of the patient. In overlapping of three-fourths of an inch and over, lameness and deformity generally occur, both in some cases being extreme. Out of the sixteen cases nine are lame, eight markedly so.

The evils resulting from the union of fragments rotated upon one another may be less evident at first sight than the lameness resulting from the overlapping, but are on that account none the less real. In this occurrence the dependent joints, which require for the perfect freedom of their action a perfect continuity of the shaft of the bone, suffer undue stress in endeavouring to accommodate themselves to the altered conditions. As Erichsen says: "The rotation outwards of the lower fragment seriously cripples the patient, as the movements of the knee and ankle are rendered almost useless in walking." This undue stress is manifested in two ways: (1) pain and weakness, or limitation of movement in the joint; and (2) organic alterations in the joint or joints. Out of the sixteen cases of fractured femur seven complain of pain in the joints, chiefly that of the knee, but occasionally in the hip and ankle also; and out of the thirteen cases of Pott's fracture four complain of pain in the subastragaloid joint, and seven in the ankle on exertion. Respecting the organic changes in joints, one is unable to draw any deductions from the above cases on account of their not extending back more than five years, whereas for their full development so as to be manifest externally they would probably require a longer time. I have, however, seen in workhouse patients some good examples of organic change in joints resulting from old fractures of the femur, and these alterations seem to be of the nature of the traumatic arthritis described by Mr. Arbuthnot Lane.⁷ After the lapse of time the lipping of the articular margins and the concurrent changes in the joint itself seriously impede the patient in the performance of his work. An examination of the museum specimens of old fractured femora will often show such a condition of traumatic arthritis.

From a consideration of the above facts it is clear that the object we should strive for in the treatment of fractures is to replace and fix the bone in its original position, and it is also plain that the conditions are such as cannot be entirely remedied by means of splints. To go on treating fractures by such means in the face of results such as the above, where in so many cases the result to the patient is so disastrous, could only be justified if there were absolutely no other means of treatment at our disposal; but fortunately there is one method which offers a prospect of perfect cure, and that is to cut down upon the seat of fracture and unite the fragments by screw or wire in the exact relation that they occupied previously. The only possible objection to this will be raised by those who are doubtful of the success of their aseptic precautions. They will probably ask, What if suppuration occurs? Yet nevertheless they open the abdominal cavity to remove ovaries and tumours which do not threaten the life of the individual, and they open knee-joints to remove loose bodies which are a source perhaps of discomfort only. Would not suppuration be as disastrous there? That line of argument is surely a wrong one to advance; the only way to decide the question should be upon grounds such as these: (1) are the present results satisfactory? and, if not, (2) does operation offer a better prospect of fixing the fractured bone in its original position? To the former question there can surely be no other answer after considering the above statistics than that the results are most deplorable, and with reference to the latter I have no hesitation in saying from the cases I have seen done thus that for replacing and fixing the bones in their proper relation, this method is infinitely superior to any means I know.

Guy's Hospital.

NATIONAL SOCIETY FOR EMPLOYMENT OF EPILEPTICS—The first annual meeting of governors was held at 12, Buckingham-street, W.C., on Monday, May 27th, the chair being taken by Mr. E. Montefiore Micholls. In a most encouraging report presented by the honorary medical staff it is stated that the experience of the first half-year from the opening of the colony has been a pleasant surprise even to those who were most sanguine as to the ultimate success of an epileptic colony.

THE TIME OF ONSET OF SYPHILITIC DISEASE OF THE NERVOUS SYSTEM AND THE THREE STAGES OF SYPHILIS.

By GEORGE OGILVIE B.Sc., M.B. EDIN., M.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS,
REGENT'S PARK.

THE division of syphilitic symptoms into primary, secondary, and tertiary is a legacy left by Ricord of very doubtful value, as it has been a constant source of confusion and a cause of much dogmatic and arbitrary handling of clinical facts. The principal upon which the distinction was made by Ricord—that only the primary stage was infectious by contact, the secondary only infectious by heredity, and the tertiary not infectious at all—has been given up by everyone. The same fate has befallen the other nosological difference introduced by him between secondary and tertiary symptoms—viz., that the former only affected skin, mucous membranes, eyes, and scrotum, while the latter attacked the inner organs. Those who, after Ricord, have tried to put this division of syphilitic symptoms on a different footing do not seem to have been happier than he was. The pathological scheme (Virchow) of dividing the symptoms into irritative and neoplastic is no better than the clinical scheme (Zeissel) of dividing them into papular and gummatous; again, the division of symptoms (Auspitz) into acute and chronic has as many shortcomings as that (Reider) into exanthematous and metastatic. Others have tried to avoid these difficulties by placing upon all these modes of dividing the symptoms of syphilis a chronological meaning, corresponding to earlier and later, and limiting the earlier period to from two to three years after the appearance of the primary sore. Those who seem to rely upon time only as a distinction (Finger) have, however, always introduced in addition some clinical characteristics of the two sets of symptoms following the primary sore, such as benignity, spontaneous recovery, universality, symmetry, &c., and consequently we are told that the secondary stage may extend considerably beyond the time arbitrarily fixed upon as its limit, and we are also told that the latest (tertiary) symptoms not unfrequently appear during the earlier (secondary) stage. In fact, with regard to some "tertiary" lesions, we are led to the paradox that they are most common in the "secondary" stage. Not one of these different divisions or classifications is fully satisfactory, still each of them contains a kernel of truth. They all aim at giving expression to an undeniable fact that in the ordinary course of syphilis a clinical difference exists between those symptoms which accompany and closely follow the eruptive stage, and those which, after a period of latency, appear later on. This fact is not expressed by Hunter's division into "local" and "general." Kaposi, dissatisfied with the unsatisfactory nature of former divisions of symptoms, tried in 1881 to return to Hunter's under the more pretentious, but practically identical, division of syphilitic symptoms into "idiopathic" and "symptomatic." He, however, had to grant in 1891 that those affections which as a rule appear after the so-called second incubation—i.e., the interval elapsing between the primary and secondary symptoms—develop and disappear in a more acute way, that there is an obvious participation of the whole organism, that they attack with predilection certain structures, and that there is a tendency to recovery even without treatment. This is what he calls the "period of eruption"; it lasts from two to eight months. It is followed, according to him, by a "period of latency" extending over several months, and what appears afterwards is comprised by him under the denomination of "period of relapses." This division expresses fairly well the ordinary course of syphilis, of which it is practically only a description. It does not give expression to the infinite variations which may occur in this most erratic disease. In fact, I believe that no classification or division of symptoms can attain this end. Perhaps, for the purpose of everyday practice, the terms secondary and tertiary, having long been in world-wide use, still express this clinical distinction between earlier and later symptoms as well as any of those which have been proposed instead of them, but the distinction between secondary and tertiary has not yet been

placed on any scientific basis. I am not therefore pleading for the abolition of these terms, but for the recognition of their merely practical and conventional character, and, at the same time, for their more careful use, so as to protect us against being driven to such incongruities as that "a large majority of the tertiary phenomena occur in the secondary period."

To get rid of the vagueness of such a division is certainly desirable, but it seems to me that nothing is gained by substituting the term "blood stage" employed by Mr. Hutchinson for the secondary period. It is well known that the blood in syphilis is infectious during the earlier stages, and this knowledge is derived from experimental, accidental, and vaccine inoculations. We further know that inoculations with the blood of patients affected with so-called tertiary symptoms have up to the present given negative results. On the other hand, we do not know in what this infectious condition of the blood consists, nor are we able clinically to decide whether this pathologically undefined condition exists in a patient or not. We consequently do not know over what period this infectious state extends, nor do we know whether its absence is proof that the virus is extinct. Therefore, to define the secondary stage as being that during which the blood is infected is of little or no practical value. That the infected state of the blood coincides with the time during which contagion and hereditary transmission are possible¹ is, again, merely hypothetical. From clinical experience it seems almost certain that the stage of possible transmission extends longer than that of possible infection; but whether this is so or not I do not see how we can make a practical use of the foregoing views. We are told, for instance, that no person should be allowed to marry during the secondary or blood stage, but that he may when it is over.² But who knows whether it is over or not? Who can ascertain whether the supposed poisoned condition of the blood exists or not? Who in the face of the impossibility of deciding this question could undertake to direct a patient on the advisability of marriage? The answer to the question of marriage must at the present day entirely depend upon our own personal clinical experience and on that of others as to the length of the interval which must elapse between the last symptom and marriage in order to practically exclude the danger of transmission. The advice given rests on experience and not on any views as to a poisoned condition of the blood. Mr. Hutchinson's personal experience, which does not agree with some other authorities, has led him to consider an interval of two years between the date of contracting the disease and marriage as sufficient guarantee against any hurt to either wife or child.³ To this rule he has seen only one exception, and he consequently has acted upon it for more than twenty years. In accordance with this outcome of practical observation he comprises by the term "secondary" the first two years.⁴ Further on, however, he thinks that we must extend our conception of the secondary stage and allow it to include a much longer period than we have hitherto done.⁵ While I fail to see that this extension is necessitated by facts, or that anything is to be gained by it, the last-quoted sentence is opposed to Mr. Hutchinson's own clinical experience and the rule derived from it, because if, after an interval of two years, infection and transmission, which are both said to be due to the condition of the blood, are practically impossible, there can be no reason for extending the blood stage. As yet we are unable to tell by the examination of a drop of blood under the microscope or by any other means whether it is infected or not; neither can we show, by combined clinical and bacteriological investigation, whether the freedom of the blood from bacilli or their toxins is in any way a guarantee against infection or transmission. When this is attained, and then only, can there be a practical meaning in the expression "blood stage."

As a consequence of the infected state of the blood Mr. Hutchinson teaches us that secondary symptoms are almost always symmetrical, while in the tertiary stage, the virus having ceased to exist in the blood, we ought not to expect the phenomena to be either general or symmetrical.⁶ Later

I shall have to refer again to the fact that the nervous affections show no more tendency to symmetry during one stage than during the other. Here, however, I should like to draw attention to the odd consequences to which this forced classification of facts must necessarily lead. Interstitial keratitis in hereditary syphilis is, according to Mr. Hutchinson, in the end always symmetrical, as well as the deafness frequently associated with it. Both these affections appear, as a rule, at the age of puberty, but occasionally much later. Still, their constant symmetry seems, according to Mr. Hutchinson, to prove that they really belong to the secondary group.⁸ Consequently, we would have here a secondary period extending over considerably more than ten years. No one will maintain that during this period hereditary syphilis remains either infectious or transmissible, and still the secondary stage was defined as being that during which the blood is infected and as coincident with that during which contagion and hereditary transmission are possible.⁹ Here theory and fact come into conflict, and in trying to stretch the latter so as to fit the former a contradiction arises which cannot be solved.

Perhaps in no chapter of our knowledge of syphilis has this confusion been more apparent than in the study of syphilitic diseases of the nervous system. It is perfectly true that in a great many even of our modern text-books the teaching is that they are the latest manifestations of the disease, and that the rare exceptions are to be regarded as precocious cases. This erroneous doctrine is not due to want of valuable investigations to prove its fallacy, but to the difficulty of getting rid of heresies once accepted as facts and covered by Ricord's great name. In fact, during the last quarter of a century numerous observers have shown that the first two years after the infection exhibit an extraordinary predominance, as far as the development of nervous affections is concerned, over any similar period during the whole course of the disease. They prove that nearly one-half of all the nervous affections met with in syphilis appear during the first two years. I am not speaking here of casual observations of early nerve disease—observations which might be traced as far back as forty years ago and more, and which have given rise to the teaching of "precocious" nervous symptoms—but of systematic statistical compilations of observations made by different men at all stages of the disease. Only these latter are of importance, as they enable us to form a definite idea as to the place which a single symptom holds in the picture of the disease.

I have lately had occasion when the subject was under discussion at the Royal Medical and Chirurgical Society to draw attention to the statistics of Braus, Mauriac, Lang, Rampl, Naunyn, Goldflam, and others. The result of Fournier's curve of so-called tertiary symptoms cannot, in the same way as the statistics of the investigators just mentioned, be applied to nervous symptoms alone, because the latter appear promiscuously with all the other tertiary lesions. It would be only after eliminating the non-nervous affections that his statistics would directly apply to the subject of this paper. Still they corroborate in a way the results of the other observers, as out of 3429 cases of so-called tertiary syphilis which reached the maximum of their frequency in the third year, 1085, or nearly one-third, belonged to the nervous system. It is not correct to state that all these writers considered the nervous diseases during the first two years as "tertiary," as some of the statistics have been drawn up from a merely chronological point of view, without taking into regard any particular classification. Besides, it is not possible to consider a disease a "tertiary" one if it appears in about 50 per cent. during the secondary period. The statistics given by Naunyn in 1888 are of greater importance than any others I have referred to. By giving some of his results as tabulated by him, I believe I am making a useful addition to the English literature on the subject, more particularly as the original is not easily accessible, and has therefore often been overlooked. He gives a series of 326 cases, including seventy necropsies, which have been judiciously selected and carefully tabulated, so as to be comparable one with the other. His object was the prognosis of syphilitic disease of the nervous system. Where the prognosis of a single case is in question, the points to which importance is attached are the following: (1) the age of the patient; (2) the age of the infection; (3) the time which has elapsed between the last other manifestation of syphilis and the appearance of the

syphilitic disease of the nervous system; (4) the duration of the nervous disease before energetic antisyphilitic treatment was adopted; (5) the form in which the disease of the nervous system appears; and (6) whether there was former treatment by mercury or not. Only those cases were selected the notes on which contained definite statements about all, or nearly all, of these points. Out of the vast literature on this subject he was only able to find 290 cases to satisfy this condition, while out of 88 cases observed by himself only 45 seemed reliable enough to be included in his tables. Tabes, general paralysis, and polyneuritis were excluded, as he had only the question of prognosis in view, and because, according to his experience in these three diseases, mercurial treatment was either useless or harmful.

TABLE I. shows the Time of the Onset of the Disease of the Nervous System after the Infection.

(For each period the percentage of the total number of cases is given.)

During first half-year.	During second half-year.	During second and third years.	During fourth and fifth years.	From sixth to tenth year.	From eleventh to fifteenth year.	From sixteenth to twentieth year.	After twentieth year.	Summary of the cases.
Per cent. 11.0	Per cent. 14.4	Per cent. 18.6	Per cent. 15.7	Per cent. 24.6	Per cent. 8.6	Per cent. 4.4	Per cent. 2.8	70 necropsies.
11.4	8.6	19.7	15.0	24.9	10.7	5.2	4.3	325 cases (inclusive of necropsies).

This table demonstrates beyond doubt that syphilitic diseases of the nervous system appear most frequently during the first year after the infection, that this frequency decreases from year to year, and that within the first year they seem to be a little more frequent during the first than during the last six months. It must also be noted that this proportion remains the same whether the results are drawn from the total number of cases or from those ending in death only. This result is in contradiction to Mr. Hutchinson's latest statement that it is very exceptional that any disease of the nervous system occurs earlier than the sixth month.¹⁰ The statistical dates lately given by Erb on syphilitic spinal paralysis are in accordance with Naunyn's numbers. Of 22 cases reported by Erb in which the date of the infection could be determined, 59 per cent. appeared during the first three years and 82 per cent. during the first six years.

TABLE II. relates to the Dependence of the Prognosis on the Age of the Patient at the Onset of the Syphilitic Disease of the Nervous System.

	0—19.		20—29.		30—39.		After 39.		Summary of cases.	
	Total number.	Percentage of cured & uncured.	Total number.	Percentage of cured & uncured.	Total number.	Percentage of cured & uncured.	Total number.	Percentage of cured & uncured.	Total number.	Percentage of cured & uncured.
Cured ...	0	...	51	47	57	47	33	41	142	45
Uncured ...	0	...	57	53	65	53	48	59	170	55

The relation between cured and uncured cases is nearly the same between the ages of twenty and twenty-nine as it is between the ages of thirty and thirty-nine, and also very nearly the same as for the total number of cases. After the fortieth year the prognosis becomes somewhat less favourable. It must be noted that under cured cases only those were registered which were considered as such by the writer. Of the improved cases those alone were counted as cured in which the improvement seemed closely to approach complete recovery. All the other improved cases are registered as not cured.

⁸ Ibid., p. 32.

⁹ Proceedings of the Royal Medical and Chirurgical Society of London, 1895, p. 110. Vide note 1.

¹⁰ Ibid., p. 89.

TABLE III. deals with the Dependence of the Prognosis on the time which has elapsed between the Appearance of the Nervous Disease and the Infection.

	During first half-year.		During second half-year.		Second and third years.	
	Total number.	Percentage of cured and uncured.	Total number.	Percentage of cured and uncured.	Total number.	Percentage of cured and uncured.
Cured	21	57	13	45	27	42
Uncured	16	43	15	55	37	58
	Fourth and fifth years.		Sixth to tenth year.		Eleventh to fifteenth year.	
	Total number.	Percentage of cured and uncured.	Total number.	Percentage of cured and uncured.	Total number.	Percentage of cured and uncured.

	Summary.					
	Total number.	Percentage of cured and uncured.	Total number.	Percentage of cured and uncured.	Total number.	Percentage of cured and uncured.
Cured	140	48				
Uncured	154	52				

Cases in which the interval was more than fifteen years were not registered at all as the number was insignificant. From the above table it seems that as long as the nervous disease appears within about ten years after the infection it is of very little moment whether it appears early or late. After the interval of ten years the prognosis becomes less favourable.

TABLE IV. shows the Dependence of the Prognosis on the Time which has elapsed between the Last Other Manifestation of Syphilis and the Commencement of the Nervous Disease.

Uncured	52	47	32	49	21	51
	From sixth to tenth year.		From eleventh to fifteenth year.		Summary of cases.	
	Total number.	Percentage of cured and uncured.	Total number.	Percentage of cured and uncured.	Total number.	Percentage of cured and uncured.
Cured	32	52	3	17	146	49
Uncured	29	48	15	83	149	51

The above table demonstrates that it is irrelevant as far as the prognosis is concerned what time has elapsed since the last syphilitic manifestation as long as the interval does not exceed ten years. After the tenth year the prognosis becomes decidedly more unfavourable.

TABLE V. gives the Dependence of the Prognosis on the Time which has elapsed between the Appearance of the Disease of the Nervous System and the Commencement of Treatment.

	Less than four weeks.		Less than three months.		Less than six months.	
	Total number.	Percentage of cured and uncured.	Total number.	Percentage of cured and uncured.	Total number.	Percentage of cured and uncured.
Cured	73	62	20	44	12	35
Uncured	45	38	23	56	22	65
	Less than twelve months.		More than one year.		Summary.	
	Total number.	Percentage of cured and uncured.	Total number.	Percentage of cured and uncured.	Total number.	Percentage of cured and uncured.
Cured	12	35	43	47	160	50
Uncured	22	65	49	53	160	50

From the above it appears that the prognosis is considerably more favourable in cases with early treatment—viz., before the end of the first four weeks. After the first four weeks cures are considerably less frequent. On the other hand, the table does not show that after four weeks the prognosis becomes continually worse as the time without treatment extends. On the contrary, after the first four weeks the chances of a cure remain the same for a period extending over more than one year. Other tables refer to the dependence of the prognosis on the nature of the nervous disease on previous mercurial treatment &c. Another point of importance elicited from the post-mortem statistics is that, with the exception of tabes and general paralysis, no syphilitic disease of the nervous system and its membranes is peculiar to a certain age of the infection. During the first year after infection gummatous disease and disease of the bloodvessels with its consequences are not rare. On the other hand, disease of the baso-cranial nerves, generally considered of comparatively early appearance, is often met with in the latest stage. This result entirely coincides with the experience of Dr. Gowers, who says¹¹ that disease of the arteries might occur at any time between the first and the twenty-fifth year after the chancre, although usually before the seventh or eighth year, that whenever it occurs it is exactly the same in appearance, and that the gummatous lesions are less common, but are found at the same period of syphilis as the arterial lesions. He, therefore, distinctly states that he knows nothing of two distinguishable forms of constitutional syphilis in the nervous system corresponding to the secondary and tertiary stage respectively. According to some, including Mr. Hutchinson,¹² the arterial disease of the nervous system belongs to the secondary or intermediate stage, while the tertiary symptoms are mostly of the nature of gummatous. This statement is not borne out either by Dr. Gowers or Naunyn. Naunyn's results were gained from a mere statistical examination of cases, unbiased by any preconceived theory as to the stages of the disease. In fact, the words "secondary" and "tertiary" do not appear at all. By his tables, the fact that nervous affections belong to the earliest manifestations of syphilis has been put on a new and firmer basis. It will be left to further investigators to repeat for each affection of the nervous system separately what has been done by him for the bulk of them, with the exception of tabes, general paralysis, and polyneuritis. Not until this has been done shall we be able to decide in what relative frequency the different affections of the nervous system appear to the age of the infection.

No more tendency to symmetry is observed in those nervous affections which set in soon after the infection than in those of later date. Mr. Hutchinson says: "If there are any forms of nervous disturbance due to the general poisoning of the blood which occurs in the secondary stage of syphilis, we should expect them to be symmetrical or even general."¹³ This expectation is not fulfilled by facts. As regards symmetry there is no distinction between earlier and later nervous affections. The paralysis of single nerves does not show any more tendency to symmetry during the first two years—secondary stage—than later. Tabes, the latest nervous manifestation of syphilis with which we are acquainted, is intrinsically symmetrical; but here, as in those cases of transverse myelitis which appear together with the first skin eruption, the symmetry is explained by anatomical peculiarities of the part affected and not by the age of the infection. The number of late syphilitic diseases of the nervous system must undoubtedly diminish as we become better able to decide what proportion of nervous diseases in syphilitic patients is due to syphilis and how much to other causes. Certainly not every nervous disease in a patient who has been subject to syphilis is of syphilitic origin. At present a tendency still prevails to accept a previous history of syphilis as sufficient evidence of the specific nature of a nervous affection, however remote its onset may be from the time of the infection or from the time of the last undoubted manifestation of syphilis. Of two cases of an identical affection of the third nerve occurring at the same time of life, say, between fifty and sixty—one in a patient with a history of syphilis dating back twenty years or more, and the other in a patient without such a history—one case will be diagnosed as late syphilitic disease and the other as probably of senile origin. The difficulty is

¹¹ Ibid., p. 90.¹² Loc. cit., pp. 37 and 42.¹³ Proceedings of the Royal Medical and Chirurgical Society, 1895, p. 69. Vide note 1.

increased by the fact that syphilitic diseases of the nervous system do not differ in appearance from those due to other causes. Dr. Ferrier very appropriately objected to Erb's paraplegia¹⁴ being raised to the rank of a disease *sui generis* as it is in symptoms identical with other cases of transverse myelitis. I have only to add that Erb himself, in his original communication, speaks with the greatest reserve on this point. Should we learn to discriminate between syphilitic nervous diseases and non-syphilitic nervous diseases in syphilitic subjects, the frequency of "tertiary" affections of the nervous system will shrink considerably, and the fact will stand out clearer still that nervous disease is an early manifestation of syphilis.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF ANGIO-NEUROTIC OEDEMA ('GRAVES' DISEASE) ASSOCIATED WITH PREGNANCY.

By C. S. EVANS, M.B., B.C. CANTAB., M.R.C.S. ENG.

A PATIENT aged about thirty years, in easy circumstances, the mother of three children and expecting her next confinement in three months, complained in April, 1893, of increasing shortness of breath, and an enlargement of the neck which had been noticed only two months. There was no exophthalmos or tremor at any time. During previous pregnancies she had, she said, "always suffered in a similar way, and also from excessive swelling of the body, face and limbs. Each labour was succeeded by extreme collapse, followed, rather than caused by a tendency to flooding." Subsequent events fully justified this description. The condition of the abdomen in May suggested hydramnios, the feet and hands increased to nearly double their ordinary bulk—so that rings had to be cut from the finger—with a soft, vascular swelling and a visible distention of vessels, recalling the appearance of subcutaneous naevi, without tenseness or blanching of the skin, and without pitting on pressure. The face was so swollen and altered as to be unrecognisable. The extremities were constantly moist and clammy. The pulse varied between 86 and 120 per minute, more on the slightest exertion. No cardiac abnormality was detected. There was slight anæmia. The urine was pale and abundant, and contained no albumen. There was no history of any severe illness except a series of sharp attacks of pain for three or four years past, attributed to gall-stones, but there had been no jaundice, and no calculi had been recognised in the motions or in the gall-bladder. Calculi in the gall-bladder were, however, felt by Mr. Knowsley Thornton in February, 1894. The bowels were habitually very constipated. The patient when in her ordinary health is lightly built, spare rather than stout, and her usual habit of mind and body is active and bright. She was restless and irritable, but never in the least anxious, from May to July. About three weeks before the confinement she and all the other inmates of the house were attacked with mild influenza. The delivery of the child was very easy, the whole process from the onset of regular pains occupying only eight hours. Chloroform was administered during the descent of the head, about twenty minutes. Ergot was given after delivery, and the uterus contracted firmly. About fifteen minutes after the return of consciousness the anticipated phenomena occurred. Pallor, faintness, and profuse perspiration suggested sudden hæmorrhage, but the uterus only relaxed slightly and there was no exceptional loss of blood. Collapse such as described followed at intervals of twenty or thirty minutes with somewhat lessening intensity, and in about an hour and a half the patient was fairly easy, though the pulse was still rapid and there was an acute pain like cramp referred to the region of the right crus of the diaphragm, perhaps due to the six or seven five-minim doses of tincture of nuxvomica which had been administered every two hours before delivery. Six hours after delivery there was a fresh and alarming attack of collapse, with considerable hæmorrhage, the pulse being 124 per minute and feeble. The uterus contracted on pressure;

sal volatile and three or four enemata of hot coffee were given, and there was no return of hæmorrhage. Convalescence was interrupted by a septic condition of intra-uterine clot, facial neuritis, neuritis of the left musculo-spiral and median nerves, and influenza cough for two or three weeks. The temperature ranged from 101.8° to 99° F. She left her bed for the first time in the sixth week after confinement. Her legs swelled almost instantly to nearly the same size as before delivery and were very painful, but this was avoided the next time by bandaging and more gradually lowering the feet. The general vascular engorgement was present in some degree at the end of September. In January, 1894, the neck measured thirteen inches. The patient was still troubled with palpitations and the abdominal pain, but relief of the latter symptom was generally obtained by castor oil. There was no cough or any special sign of progressive disease. The bodily weight was maintained, but the patient looked worn. A course of arsenic and iron was given for two months, with considerable improvement. In August, 1894, there was still some weakness and the pulse ranged over 80, but there was no swelling nor was palpitation troublesome. The excitability, tachycardia, increased perspiration, altered vascularity and nutrition of the skin, enlarged thyroid gland, and active mental condition unite in showing the case to be a phase of Graves' disease, or what has been called by Dr. Ramsay Smith¹ angio-neurotic oedema. No doubt influenza seriously modified the condition after confinement; but the most remarkable features of the case, vascular swelling and collapse, were repetitions of the history of former confinements. Since October, 1894, small patches of dry eczema have given trouble, but the general health and activity are as good as ever, anæmia is absent, and the goitre remains unchanged. I may add that none of the children present anything for remark. But in the district where this lady lived since 1891, and still lives, five women out of ten show some goitre.

Shottesbury.

A CASE OF PRIMARY SARCOMA OF THE KIDNEY IN A CHILD AGED ELEVEN MONTHS.

By M. MACKINTOSH, M.D. GLASG.

THE symptoms in this case were constipation, sickness, and gradually increasing weakness following in a few days the discovery by the child's mother of a small swelling in the left side of the abdomen. The previous history was negative and the family history uneventful. On examining the abdomen a smooth, painless swelling was found on the left side between the crest of the ilium and the floating ribs, freely movable, and easily grasped between the thumb and finger. The sensation conveyed was that of a firm, non-fluctuating globular body, apparently about the size of a small orange; it was dull to percussion. There were no distended veins to be seen anywhere, and the skin over the tumour was freely movable. Owing to the difficulty of collecting the urine—the child being a female—the presence of blood was uncertain, though on one occasion the secretion was distinctly bloody. The spleen was enlarged, but not to any marked extent, and the other organs seemed healthy. The further progress of the illness may be summed up in a few words. Sickness continued whenever food was given, sleep was absent, and the child remained quite conscious until just before her death, which took place on the eleventh day after the commencement of the symptoms. On opening the abdomen it was found that the descending colon was firmly adherent to the front of the tumour, which came into view as soon as the adhesions were torn through. The tumour itself was in like manner bound down to the posterior abdominal wall, and considerable force was necessary for its removal. It was a smooth kidney-shaped swelling about the size of the closed fist; the capsule was not adherent, and on its removal two or three dark blood-cysts were found on the surface of the organ. My friend, Dr. J. Lindsay Steven of Glasgow, kindly examined the tumour for me, and the following is his report: "On laying open the kidney you sent me the interior of the organ is found to be occupied by a large rounded tumour, which seems to have filled up the pelvis of the organ, and to have crushed the proper renal tissue aside,

¹⁴ Ibid., p. 100.

¹ THE LANCET, July 14th, 1894

so that it forms a ring round the growth. On examining a scraping microscopically the cells of the growth indicate that it has been a round-celled sarcoma."

Sister's-avenue, Clapham-common, S.W.

A CASE OF HERPES ZOSTER WITH LONG-PERSISTING NEURALGIC PAIN AND BELL'S PARALYSIS.

By G. A. VAN SOMEREN, M.D. EDIN.

A MAN, married, with no family, in good circumstances, of good physique and hitherto in good health, came under my care at the latter end of September, 1894, complaining of an eruption on the right side of the face, which extended from the crown of the head on that side to the right shoulder and clavicle, a few spots also existing over the right first rib and over the deltoid of the right arm. The eruption was fully developed and had existed for three or four days before I saw him. He complained of no pain at the time. Neuralgic pains, however, soon occurred, and then in a week or ten days from the first appearance of the eruption he showed a well-marked Bell's paralysis of the affected side. The eruption soon healed soundly, leaving very distinct scarring all over the area affected. The neuralgic pains, however, persisted, and also the Bell's paralysis, though the latter became somewhat better. Bromides, iron, strychnine, sulphate of berberine, and chloride of ammonium were all exhibited, not to mention leeches and liniments. Two and a half months from the date of the primary observation the patient was still liable to recurrent spasmodic attacks of severe and agonising pain over the mastoid process behind the right ear, these pains interfering with sleep. The appetite was good, although very occasionally he refused a meal. The bowels, at first obstinate, acted regularly. The patient walked about and was fairly cheerful. The right side of the face was smooth relatively to the opposite side, but not absolutely so. He could not close the right eye, or whistle or frown on that side. The tongue was protruded straight. The right cheek hung limply, but he had not much difficulty in moving the food about on that side of the mouth. The application of the galvanic current, begun in the early stages and long patiently persisted in, had not resulted in any perceptible improvement. What has led to my seeking to put this case on record has been the occurrence of three notices of herpes zoster in THE LANCET¹ and reperusal of the cases of Dr. Darabseth² and Mr. H. A. Spencer,³ all of which seem to show an attitude of inquiry which I desire to emphasise by the above record. No doubt in all these cases there exists an inflammation of the nerves affected, but why should this manifest itself so differently in different cases, and why should recovery occur so soon in some cases, as in that of Dr. Darabseth, and be so intractable in mine, which I judge to be longest in duration of any as regards the persistence of the neuralgic pain? In reference to this point of the severe pain the patient at first located it as over the emergence of the occipital nerve, but later it was fixed at an area exactly represented by that uncovered by hair behind the ear. The pain came and went, but while it lasted it caused him to roll about and grind his teeth with agony. It appeared at no particular period during the twenty-four hours, and analgesics like opium, exalgine, antipyrin, quinine, and the salicylates had no more than a temporary influence. One point more may need mentioning, and that is that the patient seemed to be of a markedly neurotic temperament and had had domestic worry. This seems to have introduced a hysterical element into the case, and I have since tried valerian.

ST. THOMAS'S HOSPITAL.

A CASE OF OVARIAN CYST WEIGHING OVER EIGHTY POUNDS SUCCESSFULLY REMOVED FROM A GIRL UNDER SEVENTEEN YEARS OF AGE.

(Under the care of Dr. C. J. CULLINGWORTH.)

THE following account is chiefly of interest from the success which followed the attempt to remove so large a tumour, and from the other points so clearly indicated in the remarks. It also affords another lesson, if any were needed, as to the uselessness of tapping ovarian cysts, except to relieve urgent symptoms or to diminish shock by the removal of some of the fluid contents before the operation for the removal of very large cysts. Dr. Briddon¹ has recorded a case in which an attempt at removal of a very large multilocular cyst was unsuccessfully attempted; the cyst weighed 149 lb. In the case of a woman aged twenty-six a tumour which had been growing for three years, and weighed with the fluid contents 91 lb., was removed by Mr. J. E. Abbott;² here the case also terminated fatally. It is stated that Dr. Estes³ successfully removed a tumour which weighed 125 lb. Dr. Kelly⁴ has recorded two successful operations for tumours weighing 100 lb. and 116 lb. Dr. Goodell⁵ removed one of 112 lb., Dr. Ramsay⁶ one of 95 lb., and Sir Spencer Wells one of 125 lb., and in each instance the patient recovered. These cases prove that it is possible to successfully remove these large tumours of the ovaries, but the risk is, of course, very considerable, and such tumours are rarely seen at the present day, for the diagnosis is now made at an earlier stage than was the rule a year or two ago, and operations performed while the tumour is still small as a rule are very successful. For the notes of this case we are indebted to Dr. W. E. Tinley, senior obstetric house physician.

A girl aged sixteen years was admitted to St. Thomas's Hospital on April 30th, 1895. Until the illness under discussion commenced she had always been healthy. She had menstruated once only—viz., in March or April, 1893. In the latter month the patient noticed that she was getting larger, and from that time the enlargement had continued to increase. She was tapped at Christmas, 1893, and a large quantity of fluid removed. She was tapped again in February, 1894, and a third time in May, 1894, but on neither of these occasions with any useful result. She had had no symptoms in connexion with the bladder or rectum; her appetite had been fairly good, and she had only occasionally suffered from sickness. For the previous six months she had been almost entirely bedridden, owing to the great size of the tumour. In November, 1893, she was seen in consultation by the consulting surgeon to a provincial hospital, who strongly advised that no operation should be performed. This advice the friends had hitherto acted upon. On her admission into the hospital it was noted that the patient was much emaciated and anxious-looking; her eyes were sunken, and on her cheeks was a patchy redness which easily became livid. She was very weak and could only take a few steps with assistance; she was just able to turn over in bed unassisted. The chest was very thin, the lower ribs were much everted; the thoracic viscera were displaced upwards, so that the heart dulness began at the lower border of the third cartilage, and the apex beat was best felt in the third space. Below this there was a band of (stomach) resonance before the dulness of the tumour began. The liver dulness began at the lower border of the fourth rib cartilage, in the

nipple line. The heart sounds were normal, the pulse being 140 per minute. The abdomen was enormously distended and covered by numbers of large veins running from below upwards on to the thorax. The distension was due to a cystic tumour formed of small cysts in its upper part and somewhat larger cysts in the lower; the abdomen was very tense, especially in the upper part; about three inches and a half above the umbilicus was a sulcus with its convexity downwards. There was dulness over the whole abdomen, except at the back on either side, parallel with the lumbar spines, where there was a resonant band, and above the tumour where was the stomach resonance. The greatest girth was 54½ in. There was slight œdema of the left leg. There was a trace of albumen in the urine, the specific gravity of which was 1018. Per vaginam the cervix was found to be pulled up and obliterated; the anterior vaginal wall was bulged downwards by the abdominal tumour. On May 3rd abdominal section was performed. Ether was given at first, but as it was not well taken the patient was anaesthetised with chloroform and afterwards with ether, which was given by the open method. Dr. Cullingworth made an incision, which eventually measured eight inches, in the mid-line of the abdomen. No ascitic fluid was found. The cyst was extremely adherent to the anterior abdominal wall and to the liver, spleen, and omentum. The adhesions were separated by the hand, and the cyst was tapped with a large trocar; after as much fluid had come away as was possible the fingers were introduced through the opening made by the trocar and other cysts were emptied by breaking down septa with the finger. The patient was much collapsed at this stage of the operation, and one-twentieth of a grain of strychnine was given hypodermically, followed by twenty-five minims of ether and a second hypodermic injection of strychnine (½ gr.). The tumour arose from the left ovary; the pedicle was small: there was no burrowing between the layers of the broad ligament. The pedicle was tied in the ordinary way, and the cyst was removed. The uterus and right ovary were healthy but ill-developed. A hot boracic douche was given and the abdomen closed by silkworm gut sutures passing through the whole thickness of the abdominal wall. The wound was covered with dry dressings, and the patient, who had recovered a little after the hypodermic injections, was lifted into bed and taken back to the ward. The weight of the tumour was between 80 lb. and 90 lb. (The cyst, with as much of its contents as could be collected, was found to weigh 79½ lb., but much fluid, of course, escaped. A nearer estimate of the actual weight of the tumour was arrived at by deducting the weight of the patient a week after the operation (the earliest period at which she could be placed in the weighing-chair)—i.e., 79½ lb. from her weight the night before the operation—i.e., 170 lb. The difference is 90½ lb., or 11 lb. more than her entire body-weight.) At nine o'clock on the night of operation she was extremely collapsed. A hypodermic injection of one-twentieth of a grain of strychnine was given, followed in three-quarters of an hour by a hypodermic injection of twenty-five minims of brandy, which was repeated at 10.45 P.M., 11.45 P.M., and 4 A.M. next morning. Another hypodermic injection of one-twentieth of a grain of strychnine was given at 1.15 A.M. She had one fluid ounce of brandy by the mouth before 3 P.M., and four fluid ounces between 3 P.M. and 8 A.M. next morning. She also had a tablespoonful at 8 P.M., 2 A.M., and 8 A.M. in three ounce nutrient enemata. She had fortunately no sickness whatever. She passed flatus naturally during the night. Next morning the skin was dry and warm, and the pulse, which previously could not be counted, was 136. The day after the operation the patient passed urine and faeces naturally. She slept a little during the night after the operation and fairly well the next night. After this, convalescence was uninterrupted; the stitches were removed on the eighth day, the wound having healed perfectly. On the fifteenth day after the operation she was on the couch for a short time. She had lost her livid colour and was daily gaining strength and increased power to move about. The abdomen, for the first few days hollow in appearance from retraction of the parietes, was now assuming a more natural contour. The gain in weight during the first week after the operation could not, for obvious reasons, be accurately determined. It was probably inconsiderable; but the gain during the second week was 5 lb., and during the third exactly the same.

Remarks by Dr. CULLINGWORTH.—The interesting points in this case are: (1) the age of the patient; (2) the enormous

size and weight of the tumour, especially in relation to the size and weight of the patient; and (3) the advice given by the surgeon who visited her. The first tapping appears to have given considerable relief, but at subsequent tapplings the trocar evidently entered small cysts with viscid contents, with the result that little or no fluid escaped. Under these circumstances there seemed nothing for it but to watch the patient die. Her size became so great that she had been bedridden for some months previously to her admission. Her friends happened to hear of someone living in another part of the same county who had had an unusually large tumour removed, and the result of a visit to this patient was a determination to send the girl up for operation. They were doubtful whether she would survive the long journey, but she bore it fairly well. The case was one that only a strong sense of duty would lead one to undertake. It was impossible not to recognise the peril that must necessarily attend the removal of a tumour so large as to exceed in weight the rest of the patient's body. Manifestly, however, the girl could not be allowed to die without an effort being made to save her. It was foreseen that a large incision would be required, as the tumour was made up of a multitude of small cysts, and it was therefore impossible to reduce its size to any considerable extent before removal. The anterior surface, as invariably happens in these tumours of extraordinary size, was firmly adherent to the abdominal wall and to some of the abdominal viscera. The pedicle, fortunately, was not inconveniently broad. Once during the operation, and two or three times during the night following, alarming symptoms of collapse presented themselves. Happily on each occasion the patient responded to stimulation, and the danger was averted. Since the first twenty-four hours the progress of the patient has been uninterrupted. For the first fortnight the pulse continued to be abnormally rapid, but after that time it gradually became slower, and no doubt it will soon be normal. I have thought it worth while in recording this case to give the precise details (obtained from my house-physician, Dr. Tinley) as to the quantity of stimulant administered and the various other means adopted to prevent death from shock. The case calls to mind one that was described in THE LANCET about four years ago⁷ in which the tumour I removed was still larger. In that case the delay in operating was due to the patient's own obstinacy.

ROYAL BERKSHIRE HOSPITAL.

CASE OF BILATERAL PARALYSIS OF THE CRICO-ARYTÆ-NOIDEI POSTICI ASSOCIATED WITH TABES DORSALIS; ASPHYXIA; TRACHEOTOMY; RECOVERY; REMARKS.

(Under the care of Dr. FRANCIS HAWKINS.)

FOR many years the subject of paralysis of the abductors of the larynx in connexion with various affections of the nervous system has been under the consideration of neurologists and laryngologists. Many explanations have been offered and much has been written on the subject. The question was recently discussed in the columns of THE LANCET in an able paper by Dr. Cagney,¹ and the greater liability of the abductors to paralysis was ascribed to the absence of a cortical centre in their case and the connexion of the adductors with such a centre. The history of the investigations into this condition is given in that paper, and the arguments for and against other theories are fairly and impartially discussed.

A man aged forty-two years was admitted to the Royal Berkshire Hospital on Aug. 7th, 1894, complaining of hoarseness and cough which had been present on and off for four years, but latterly was more constant. Fifteen years previously the patient had contracted syphilis; he was now married and had healthy children. He was a tall, well-built, healthy-looking man. There was marked myosis of both pupils, but slightly more in the left. Argyll-Robertson's symptom was present. The ocular movements and fundi were normal; there was no nystagmus. The patient said that occasionally he saw specks before the eyes. Tactile sensibility was normal over the whole body, but there was marked analgesia. Sensibility to heat and cold was impaired on the legs. Muscular sense appeared to be normal. There was a feeling of numbness in the hands and feet, and occasionally

⁷ THE LANCET, May 2nd, 1891.

¹ THE LANCET, June 16th, 1894.

there were pains in the abdomen, but not in any other part. The knee-jerks were absent, but the plantar and other superficial reflexes were present. The gait was only slightly ataxic. There was some unsteadiness when the heels were placed together and the eyes closed, but the patient did not fall. As to the larynx, the voice was only very slightly rough; the epiglottis was normal, but the vocal cords were seen to be lying close to each other in the middle line. The heart and aorta were normal. The lungs were somewhat emphysematous. The urine contained a trace of albumen, and sometimes incontinence was complained of. On Aug. 10th, at 5.30 A.M., the patient suddenly became greatly distressed with his breathing and quickly became asphyxiated. Tracheotomy was at once performed, and instant relief followed. For several weeks the patient was kept under observation. An india-rubber tube was then supplied to him, and, being instructed how to take it out and replace it, he was discharged. In March, 1895, the patient came for a new tube. He stated that his health had improved. He had gained in weight. Laryngoscopic examination showed the vocal cords to be in the same position (abduction) as on former examinations.

Remarks by Dr. F. HAWKINS.—Bilateral paralysis of the abductors is rare and is always attended with danger. Dr. Percy Kidd, writing in *THE LANCET*,² states that evidence is accumulating to show that the abductors are specially liable to paralysis. This form of paralysis occurs as a central affection in the course of bulbar paralysis, multiple sclerosis, and tabes dorsalis. It may also be due to pressure within the thorax, upon the vagi or the recurrent, as in cases of aneurysm, cancer of the œsophagus, and enlarged bronchial glands due to malignant disease or pulmonary tuberculosis. It is also met with in hysteria and as a sequel to laryngitis, diphtheria, and typhoid fever. Strümpell says that it may be due to ankylosis in the crico-arytænoid articulation. It is met with more frequently in men than in women. In some few instances it is recovered from, but tracheotomy usually has to be performed; by this means life has been prolonged for nine and for fifteen years. In sixty cases, tabulated in *THE LANCET* for 1887,³ only two were associated with tabes dorsalis for certain, one case being doubtful. It would, therefore, appear to be rare. An interesting case of bilateral paralysis is recorded by Boulay and Mendel⁴ occurring in a man four years after the primary infection of syphilis, when he was seized with right-sided paralysis of the face, arm, and leg, with loss of speech; the hemiplegia passed off in four months, when right oculo-motor paralysis developed; the voice was then hoarse, and dyspnoea was present on exertion; the vocal cords were found to be abducted; the cause assigned was syphilitic pachymeningitis. There is no doubt that syphilis is a frequent cause of this form of paralysis. In the sixty cases referred to, six were due to this, one occurring in the secondary stage, and one was due to syphilitic tumour of the gullet.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Micro-organisms in the Healthy Nose.

AN ordinary meeting of this society was held on May 28th, Mr. HUTCHINSON, F.R.C.S., President, being in the chair.

Dr. ST. CLAIR THOMSON and Dr. R. T. HEWLETT read a paper on *Micro-organisms in the Healthy Nose*. They stated that they had been working at the bacteriology of the upper air passages. Commencing with the nose, they first of all investigated its bacteriological condition in a state of health. The results arrived at contrasted in a striking way with those obtained by the majority of previous observers. About 500 litres of air, bearing on a low average 1500 organisms, were inspired every hour. As all, or at least the greater portion, of this came in contact with the moist mucous membrane lining the tortuous passages of the nasal fossæ, it had been taken for granted that the interior of the nose must show a rich profusion of micro-organisms. This

conception was now widely adopted, and its general acceptance probably accounted for the scarcity of recorded observations of bacterioscopic examinations of the nasal cavity in a state of health. The literature of the subject was gone over in chronological order. Only two papers had been found devoted entirely to the bacteriology of the normal condition; all other references to the healthy state were only made incidentally in the course of researches on diseased conditions. The most diverse results had been arrived at both as to the varieties and abundance of organisms met with. Only two authorities—Löwenberg and Hajek—found a scarcity of bacteria in the nose; others recorded a greater or less variety and profusion. One observer found the streptococcus of Fehleisen present in one out of every five healthy individuals, and another found the diplococcus pneumoniae (Fränkel-Weichselbaum) once in every four observations. This latter observer frequently met with the bacillus pneumoniae (Friedländer), the streptococcus pyogenes, and the staphylococcus pyogenes aureus, and not only in considerable numbers, but sometimes in pure culture. The method of examination adopted by Dr. St. Clair Thomson and Dr. Hewlett was that of cultivations on agar and cover-glass preparations stained with gentian violet. No attempt was made to differentiate the organisms met with. This research only dealt with the presence or absence of bacteria, and a simple method was adopted to ensure uniformity of comparison. Thirteen healthy individuals were examined. Twenty-seven cultures and fourteen cover-glass preparations were made from the vestibule of the nose. Seventy-six cultures and thirty cover-glass preparations were made from the mucous membrane of the nasal cavity. The results were summarised as follows. 1. In all bacterioscopic investigations of the nasal fossæ, in all researches as to the action of nasal mucus, &c., a clear distinction must be made between the vestibule of the nose and the proper mucous cavity. The former was lined with skin and was furnished with hairs and with sudoriferous and sebaceous glands; it was not part of the nose cavity proper, but only led to it. 2. The neglect of this distinction might account for the discrepancy in previous observations on the subject. Contamination with the lining of the vestibule was difficult to avoid even when this source of error had been realised. 3. In the dust and crusts of mucus and debris deposited among the vibrissæ of healthy subjects micro-organisms were never absent. They were rarely scanty in number; as a rule they were abundant. 4. On the Schneiderian membrane the reverse was the case. Dr. St. Clair Thomson and Dr. Hewlett did not assert that micro-organisms were completely absent; obviously some must occasionally occur, but under normal conditions they were never plentiful; they were rarely even numerous, and in more than 80 per cent. of their observations no organisms whatever were found, and the mucus was completely sterile. 5. The occurrence of pathogenic organisms must be so infrequent that their presence on the Schneiderian membrane could only be regarded as quite exceptional. Clinical experience bore out the above conclusions, and their applications in practice were sufficiently obvious. In conclusion, they touched upon the problems suggested by the above, and referred to the questions they were at present engaged in solving.

Mr. SPENCER WATSON said that it would appear from their experiments that all, or nearly all, of the micro-organisms contained in the inspired air were arrested in the vestibule by the moist surfaces and vibrissæ there present. If this be so it testified to a very beautiful provision for purifying the air, but it was perhaps a little premature for us to decide that the great majority of the microbes in the air were really thus arrested. In children the vestibule was very small and ill developed as compared with the adult, and the vibrissæ were represented only by some down. It was difficult to conceive that in children the micro-organisms could be arrested by that ill-developed vestibule. The mucus taken from the interior of the cavity proper had been taken only from the accessible parts. The greater portion of the interior of the cavity proper was inaccessible in the sense in which they employed the term, and it seemed very possible that the stream of air carrying the microbes might pass over the smooth anterior surfaces and yet become deposited upon the rougher and more extensive parts of the turbinates, which had a distinctly different character in the adult as compared with the child. He asked in what way they thought the nasal cavities were self-cleansing—whether by the filter which was provided in the vestibule, or whether we were to understand that there were certain processes going

⁴ Archives Internationales de Laryngologie, July and August, 1894.

on in the deeper parts by which micro-organisms which had passed the vestibule were neutralised, absorbed, or taken up by phagocytes. There was a sort of hint given that the bacilli or cocci were being devoured by phagocytes. Did they credit the nose with possessing a large proportion of defensive phagocytes? It was a source of satisfaction to him, however, that they had come to the conclusion that the mucous lining of the nose was to a large extent aseptic. He had often been struck by the facility with which wounds in that situation healed and how seldom it was for surgical fever or septic infection to follow operations there. It must not be forgotten, however, that wounds of the face—including the nose, mouth, &c.—had a tendency to heal very rapidly even in the absence of antiseptic precautions, and it was possible that this tendency might explain the absence of surgical fever after operations on the nose.

Dr. FELIX SEMON said that the fact that so few bacteria had been found was astounding. He agreed that there was no need to seek to render the cavity aseptic before operating, but it was advisable to use local antiseptics afterwards, because after these operations lacunar tonsillitis sometimes followed though the pharynx was previously healthy. Tuberculosis of the nasal mucous membrane was exceedingly rare. He had only met with two or three cases. There certainly appeared to be some ground for the suggestion that the nose was anatomically antiseptic. It was an extraordinary thing that the naso-pharynx, which was a cul-de-sac apparently excellently adapted for the development of micro-organisms, did not show any such tendency. Years ago, when performing the then popular operation for the removal of adenoid growths in children, he always used to cleanse the naso-pharynx by means of some antiseptic solution; but the number of ear accidents which followed this procedure made him give it up, and since he had abandoned the practice, employing practically no after-treatment whatever, these complications had not occurred. This, from a practical point of view, argued against the presence of pathogenic micro-organisms.

Dr. ALLAN MACFADYEN said it was not an easy matter to make a bacteriological examination of the nasal cavities without the possibility of some fallacy creeping in. In this instance the conjunction of a rhinologist with a bacteriologist had added greatly to the value and the accuracy of the results. The preconceived notion of most medical men was that the nasal cavities swarmed with microbes. From the nature of things one would be tempted to think that such was the case, and the most interesting part of the paper was precisely that which proved that this was not so; that while the vestibule contained a large number of microbes the mucous membrane of the cavity proper had few or no organisms. No doubt the discrepancies which had occurred in the results obtained by other observers were largely due to the want of a clear distinction between the vestibule itself and the cavity proper. These results were striking because they had taken the maximum number of micro-organisms likely to enter with the inspired air during an hour, and they had shown that the vast majority of these had disappeared before they had reached the upper portions of the nose. It showed what an efficient filtering apparatus the nasal cavity was for impurities of all kinds. No doubt a good part of this result might be due to the mechanical action of the vibrissæ and the presence of sticky mucus; still a certain number of organisms must pass up, and the question arose as to what became of them. That brought up a very interesting question as to the possible action of mucus upon organisms. It might be that the mucus did not furnish a suitable soil for the growth of bacteria and consequently that they degenerated and died, or that the mucus itself had a bactericidal action upon bacteria. He referred to the investigations of Santorelli in respect of sputum. He found that most organisms died or lost their virulence under its influence with the exception of the diphtheria bacillus. Still, there was a possibility of pathogenic material remaining for a very long time in the nasal cavities.

Dr. HABERSHON said the paper possessed a double interest, especially to rhinologists, in its bearing on operations, and the question how far the pathogenic organisms could be absorbed in this situation. There was also a special bearing on the clinical and pathological side as to how far absorption might take place from the healthy mucous membrane. Some years ago when he was working at Vienna a view was very generally held that all the portions of the mucous membrane that were covered with ciliated epithelium were not the first to be infected, this being explained on the ground of the

mechanical action of the cilia in moving on the organisms and so preventing absorption. There were certain pathological facts in support of that view. Some years ago he worked out the question with regard to the larynx, and he found that those parts of the larynx that were covered with ciliated epithelium were not so frequently affected, at any rate in the first instance. Possibly the same cause might prevent the nasal mucous membrane from being the seat of absorption in respect of pathological micro-organisms. He had recently met with four successive cases in which the tonsils were evidently the seat of absorption of the tubercle bacillus and probably the starting point of the whole disease.

Dr. HEWLETT, in reply, said that, although it was mentioned that many microbes were arrested by the vibrissæ, it was not stated that this was the essential factor which prevented the microbes getting into the nose. With regard to the method of self-cleansing this was a point which was engaging attention, and there were, of course, several factors to be considered. One important factor was that suggested by Dr. Habershon—viz., the protective power of a ciliated surface. Then, too, there was the question of phagocytosis, but this was probably subsidiary. Another point, probably of great importance, and which some experiments seemed to bear out, was that the nasal mucus appeared to be a very bad nutrient medium for microbes. This was borne out, also, by certain experiments carried out in respect of vaginal mucus. This quality, at any rate, prevented the rapid multiplication of the microbes, such as might be seen in the mouth, &c. Then there was the mechanical action of the mucus, which was constantly trickling over the surfaces and must necessarily carry down microbes and dust. Similar observations had been made in respect of the freedom from microbial invasion of the conjunctival culs-de-sac. With regard to the arrest of bacteria they had made a good many observations as to this, but they had been rather a failure.

Dr. ST. CLAIR THOMSON, in reply, said that they had not attempted to deal with the character of the bacteria at all. He had looked at a good many children's noses, and had noticed that they were all provided with down, which often had some dust upon it and was usually kept very wet by mucus. As to the accessible regions, the back part of the nose might be bacteriologically accessible, but though the posterior part of the nose might appear to be accessible, it was difficult to imagine that any microbes could escape the anterior part and lodge behind. He did not wish to discuss the pathology of lacunar tonsillitis after operation, although he had read the papers referred to by Dr. Semon, and was aware that French observers regarded it as a septic infection. Sir Joseph Lister used to point out that empyemata, which discharged through the bronchi through which the patient breathed very seldom, became septic, which he ascribed to the ciliated epithelium, and he compared this with what took place when the empyema communicated with the air through a fistula. In this connexion he used to insist upon the necessity of keeping the ear aseptic in cases of fractured skull, holding that the mischief was mostly of a septic nature. He disregarded the Eustachian tube because it was lined by ciliated epithelium.

CLINICAL SOCIETY OF LONDON.

Thickened and Contracted Mesentery simulating Tumour in a case of Cirrhosis of the Liver.—Splenio Abscess associated with Hepatic Suppuration and Death from Pyæmia.—Recovery from Tuberculous Meningitis.—Calculus of Kidney associated with Simple Growth in Renal Pelvis.—Annual General Meeting.

THE last ordinary meeting of this society for the present session took place on May 24th, Mr. LANGTON, Acting President, being in the chair.

Dr. F. LUCAS BENHAM read a paper upon a case of Thickened and Contracted Mesentery simulating Tumour in a case of Cirrhosis of the Liver. The patient was a man aged fifty-five years suffering from advanced cirrhosis, with a history of former excess of alcohol and of an attack of jaundice some years ago. He had a large amount of ascites and was almost in *extremis* when first seen. Paracentesis was performed to give relief, and it did so, but he died two days after. The unusual feature of the case was that, during paracentesis, when thirteen quarts of clear reddish fluid had been removed, a large, irregular, rounded, solid tumour was noticed fixed in

the centre of the abdomen, the nature of which was doubtful, as it presented some of the characters of a malignant growth. At the necropsy about a gallon and a half of remaining fluid escaped. There was no acute peritonitis, but the surface of the peritoneum was without gloss. The liver was typically cirrhotic without perihepatitis. The kidneys were normal. The tumour discovered during life was found to consist of the enormously shrunken mesentery, which was shortened, thickened, and loaded with fat, the small intestines being huddled up compactly together. The omentum was thickened and condensed into the shape of a sausage. The condition was evidently that of a form of chronic peritonitis, but one which had not been described, as far as Dr. Benham knew, in connexion with cirrhosis of the liver, though a slight degree of the affection—viz., condensation of the omentum—was not uncommonly met with post mortem in cases of this disease. The points of interest seemed to be: (1) the question of the pathology of the complication, especially in its relation to alcoholism and cirrhosis; and (2) the practical fact of the presence of a tumour whose nature might be mistaken.—Mr. BARKER was interested in the case, as it possibly explained one which he had some difficulty in understanding. A man aged forty-eight years entered University College Hospital with obscure symptoms of intestinal obstruction of fifteen years' duration. He had passed pus per rectum, and there was difficulty with the bowels. In the abdomen a distinct sausage-shaped tumour was felt in the mid-line lying transversely below the umbilicus. The length of time during which this tumour had existed negatived malignant disease, and some benign growth of the colon was suspected. He performed laparotomy a fortnight ago, and found a much thickened parietal peritoneum; the intestines were thickened, and the mesentery enormously so. The swelling was found to be composed of this mesentery, which belonged to the descending colon.—Dr. HALE WHITE had seen several cases of this condition, which was a well-known form of chronic peritonitis in which the omentum became puckered up and was mistaken for malignant disease. Usually on careful percussion a line of resonance could be distinguished between it and the liver. The affection was often connected with granular kidney, but the liver as a rule was not cirrhotic, though he had met with one or two instances of this association.—Dr. BENHAM, in reply, said that as a rule in cases of cirrhosis the mesentery was fatter. The late Dr. Fagge had stated that the majority of cases of chronic peritonitis were of this form and not of the exudative variety.

Dr. SIDNEY PHILLIPS related a case of Suppurative Pylephlebitis with Abscess in the Spleen and a Foreign Body in the Mesenteric Vein. The patient was a man aged fifty-two years who had had rheumatic fever at the age of seventeen, had suffered from asthma, and had been a free spirit-drinker. On Aug. 15th, 1894, when in good health, he was suddenly seized by a violent rigor; rigors and sweats succeeded on the four following days, and after an interval of eighteen days he had another rigor. He was admitted into St. Mary's Hospital on Sept. 11th. The liver and spleen were then very greatly enlarged, but both organs were hard and without signs of abscess; the respirations were 40 a minute, and there was much bronchitis. There being evidence of left pleural effusion, an exploring needle was introduced and the fluid was found to be pure blood; the temperature throughout the patient's stay in hospital was 101° to 102° F. Microscopic examination of the blood (from the finger) showed only a great decrease in the number of red corpuscles. Ten ounces of pure blood were removed from the pleura by aspiration, relieving the dyspnoea, but the patient's septic condition advanced; he became delirious and more exhausted, the fever persisted, the signs of enlargement of the liver and spleen decreased, and he died on Sept. 17th. At the necropsy the portal vein was found full of pus, which extended into its ultimate ramifications in the liver, so that on section of any part of the organ pus exuded, though it contained no localised abscess. The spleen was almost destroyed by three large abscesses in its substance. The mesenteric veins were full of pus, and in the interior of the upper part of the inferior mesenteric vein were discovered two bristles three-quarters of an inch and a quarter of an inch long; they were probably parts of one original bristle which had broken. There was no ulceration or disease of any part of the intestine or stomach. In commenting on this case Dr. Sidney Phillips remarked it was evident during the patient's life that there was suppuration in some part of the abdominal

cavity, but no abscess could be detected in the liver or spleen, and it seemed doubtful where the pus formation had occurred. The cause of the general suppurative pylephlebitis found at the necropsy was in all probability the bristles seen in the inferior mesenteric vein; they had probably been swallowed at some previous time, and must have passed, probably as one bristle, through the wall of the intestine and that of the vein, though no trace could be discovered of their passage. The splenic abscesses probably resulted from the pyæmic state ensuing while the splenic vein was intensely engorged with blood from the thrombosis of the portal vein. A case of traumatic pylephlebitis somewhat similar to this had been recorded in 1842. In that case a fish-bone passed through the stomach wall and became impacted in the superior mesenteric vein. It would be well in future cases of splenic abscess found post mortem without any evident cause to search for any foreign body in the intestinal veins. Among other points of interest in the case recorded was that the pleural effusion was hæmorrhagic, probably on account of the pyæmic condition of the blood and the disturbance in the function of the spleen. It was also noteworthy that when the spleen became purulent it was so much softened that it gave the erroneous impression that its enlargement had lessened.

Dr. SAMUEL WEST described a case of Recovery from Tuberculous Meningitis. The patient was a female child aged two years and six months who was admitted to hospital on account of frequent vomiting, loss of appetite, and constipation. She had been quite well until April 3rd, 1894, when she became febrile and began to vomit frequently. On the 5th she had a fit, became stiff, and her mother said she was distinctly convulsed. She remained in this condition for two days, when she rallied somewhat, but hardly slept at all, picked her face a good deal, and seemed to dread being touched. She was admitted on the 11th. She lay on the left side with her head drawn back, and took little notice of her surroundings. The eyebrows were slightly contracted, the eyes half open, and the pupils and the movements of the eyes normal. She was continually grinding the teeth. The pulse was 165 per minute and the evening temperature rose to 103° F. On the 14th a patch of broncho-pneumonia was found at the right apex. The child continued delirious and on the 20th slight strabismus was observed. The pulse had fallen to 120 and the temperature was subnormal. On the 23rd the right pupil was seen to be smaller than the left. On the 28th he examined the eyes and found a double optic neuritis, most marked on the left side. On May 2nd the patient was semi-comatose, vomited constantly, and had to be fed through the nose. The pupils scarcely reacted at all to light. On the 4th the breathing became very irregular and only numbered about 8 to the minute; the pulse was 54 and the temperature was subnormal. During the night the child had an attack of twitching all over, and appeared to be dying from what seemed to be tuberculous meningitis; however, from this time she began to improve, though at first slowly and with many relapses, but the twitchings continued, and there was pain in the head. During the month of June the symptoms varied from day to day, but with gradual improvement, though the retraction of the head and stiffness of the legs continued. The knee-jerks were absent, as they had been for some time. By July 18th the optic neuritis had almost disappeared, but the child did not seem able to see much, though the pupils reacted to light. On Sept. 6th the patient had a relapse, but by the 19th this had subsided. By Oct. 26th she was able to understand what was said to her and was able to sit up a little. By Dec. 1st she could walk with a little assistance. In February she was running about actively, could see perfectly, and spoke plainly. Her health at the present time was excellent. During this child's illness (June 19th) her little brother, aged nine months, was admitted into the hospital with a history of having been ill for three weeks with vomiting and fits. On admission there was marked retraction of the head, tense fontanelle, varying strabismus, and frequent vomiting. The discs were normal and the temperature not raised. This child died on Aug. 16th, and post mortem the lesions of tubercle were not very numerous, nor was the amount of inflammation great. Dr. West pointed out that as this child did not die until the tenth week it might be presumed that the inflammation was not very severe or extensive. As to the diagnosis in the first case, he admitted that in the absence of a necropsy this must be a matter of opinion and judgement. The evidence of the meningitis being tuberculous in many cases was not strong, but considering that in the majority of cases of tuberculous

meningitis the diagnosis was confirmed at the necropsy it was not really as difficult as it might seem. The special interest of the case lay in the fact that two children of the same family were attacked at the same time, and the same diagnosis was made in each case. The one patient died and the diagnosis was confirmed at the necropsy. The presumption was, therefore, that the diagnosis was correct in the case of the other patient, who recovered. Both cases ran a somewhat unusual course.—Dr. CHARLEWOOD TURNER said that it would have been more satisfactory if bacilli had been found, for very similar lesions might be produced with different micro-organisms, and the cases related were certainly not typical of tuberculous meningitis.—Dr. GLOVER said that the diagnosis of tuberculous meningitis must be accepted with scepticism.—Dr. HALE WHITE, replying for Dr. West, said that the late Dr. Fagge advised the use of hydragryum cum creta in these cases.

Mr. W. H. BATTLE read the notes of a case of Calculus of the Kidney associated with Simple Growth in the Renal Pelvis, for which nephrotomy and subsequently nephrectomy had been performed. The patient, a man aged fifty-one years, had been under treatment in St. Thomas's Hospital in 1893 for hæmaturia which had first been noticed in April of the previous year. The hæmaturia was constant on admission, and there was a history of renal calculi seven years before. Mr. Anderson, under whose care the patient first came, explored the bladder, but no disease was found there. Blood was issuing from the left ureter. In consequence of the illness of Mr. Anderson the patient came under the care of Mr. Battle, who agreed in the diagnosis of calculous pyelitis with new growth, and explored the kidney from the loin on Feb. 23rd. Several oxalate of lime calculi were removed, and a villous growth growing from the lower anterior aspect of the renal pelvis was scraped away. It presented no signs of malignancy, but was reported as squamous epithelioma on examination. The patient left the hospital in April, the operation having quite arrested the hæmaturia. He resumed work on June 25th, but in August noticed that blood was again appearing in the urine. This was at first only at intervals, once a week or so; then it became more frequent until Christmas, 1893, when the urine always contained blood. From that Christmas until July, 1894, the hæmaturia was profuse and constant, so that he was obliged to keep his bed, and only left it to come up for admission on the 19th. He had become very anæmic as contrasted with his appearance a year before, but was not losing flesh. The urine was always of a deep purple colour. He had passed some small stones per urethram during the previous twelve months. The kidney on the left side was enlarged somewhat and adherent to the scar, and there was a little pain on manipulation. There was much albumen in the urine, which during the twenty-four hours after admission measured forty-one ounces. On Aug. 15th the left kidney was removed from the lumbar region, the delay before operating having been purposely made in order that the man might recruit his strength. Hamamelis appeared to diminish the loss of blood for a time, and the kidney had become less easily felt; the highest temperature had been 99° F. on one or two occasions. The kidney was found at the operation to be extremely adherent to the old scar, and on separating the adhesions a small abscess was found communicating with the renal pelvis and containing one or two stones. The adhesions were very dense on the anterior and lower surfaces of the organ, and it was necessary to increase the incision. After removal the capsule was stitched over the stump and the wound closed, with a drainage-tube passed down to this. On the 17th there was no blood, pus, or albumen in the urine. A month later the wound was closed satisfactorily and the quantity of urine passed was normal, there was less anæmia, and he was gaining strength rapidly. He went home on Sept. 19th, but has been seen recently and is in good health. The kidney removed showed some thickening where involved in the scar, which extended so as to form a tumour that projected into the pelvis. The surface towards the pelvis was papillated and firm. Sections examined under the microscope showed no new growth in this part. Mr. Battle said that the most unusual character of the growth was a reason for bringing the case before the society. He had expected at the first operation to find an epithelioma, but the examination showed a growth of innocent nature, and he had felt justified, therefore, in removing it as thoroughly as possible by scraping. The report of the pathologist that it was squamous epithelioma came as a surprise, and he regretted then that he had not

done nephrectomy at once. When the patient again came under care there was a sufficient reason for removal of the organ in the constant and prolonged hæmorrhage, but the clinical signs were still those of innocent growth. Subsequent examination had caused the pathologist to alter his verdict in favour of simple papilloma.

The business of the annual meeting was then proceeded with. The membership of the society was now 546, and the losses by death included its President (Mr. Hulke), one of its Vice-Presidents (Sir George Buchanan), a late Vice-President (Mr. Arthur Durham) and Dr. Maunsell. Allusion was made to the successful working of the new arrangements for the exhibition of clinical cases and to the appointment of a committee to investigate the clinical value of the antitoxin of diphtheria. The Treasurer reported that the finances of the society were in a satisfactory state.

The following distinguished physicians and surgeons were elected honorary members of the society:—Sir G. M. Humphry, M.D., F.R.C.S., LL.D., F.R.S.; J. Burdon Sanderson, M.D., F.R.C.P. Lond., D.C.L., LL.D., F.R.S.; Samuel Wilks, LL.D., M.D., F.R.C.P. Lond., F.R.S.; Dr. Carl Gerhardt, Dr. Theodor Kocher, Dr. Just Lucas-Championniere, Professor H. Nothnagel, and Professor Rudolf Virchow, D.Sc. Cantab., D.C.L. Oxon.

The following were elected office-bearers for the ensuing year:—President: Thomas Buzzard, M.D. Vice-Presidents: Frederick Taylor, M.D., T. T. Whipple, M.B., Thomas Barlow, M.D., Robert William Parker, William Henry Bennett, and Rickman John Godlee, M.B. Treasurer: William Miller Ord, M.D. Council: W. H. Allchin, M.D., W. P. Herringham, M.D., Constantine Holman, M.D., Patrick Manson, M.D., Frederick Walter Mott, M.D., H. Montague Murray, M.D., Sidney Phillips, M.D., G. Newton Pitt, M.D., Seymour J. Sharkey, M.D., Edward Markham Skerritt, M.D., Dawson Williams, M.D., C. A. Ballance, M.B., M.S., W. Watson Cheyne, M.B., W. Bruce Clark, M.B., A. Pearce Gould, M.S., C. R. B. Keetley, W. Arbuthnot Lane, M.S., Bilton Pollard, A. W. Mayo Robson, and J. Bland Sutton, Honorary Secretaries: W. Hale White, M.D., and G. H. Makins.

HARVEIAN SOCIETY OF LONDON.

Splenic Anæmia.—Exhibition of Cases.

A MEETING of this society was held on May 16th. Sir JOHN WILLIAMS, Bart., M.D., being in the chair.

Dr. LEONARD GUTHRIE showed an infant aged one year and eight months suffering from Splenic Anæmia of eight months' duration. The anæmia was profound. The spleen could be felt half an inch above the umbilicus. The blood contained about 36 per cent. of the normal amount of red corpuscles, and a similar reduction in the percentage of hæmoglobin was found. There was a slight increase in the number of white corpuscles, but it did not amount to leucocythæmia. The cervical and inguinal glands were slightly enlarged. The child was rickety, but showed no symptoms of hereditary syphilis, malaria, or tubercle. The condition was slowly progressing and had resisted a variety of forms of treatment. Recovery in such cases was almost hopeless. Dr. Guthrie therefore suggested that splenectomy might afford a chance of life and invited discussion on the point.—Dr. CLIFFORD BEALE mentioned a recent case in which enlargement of the spleen and extreme anæmia developed in a child aged eighteen months after a severe attack of bronchopneumonia. The splenic enlargement took place rapidly and with a temperature of a hectic type, with intervals of apparent improvement and normal temperature. Corpuscles and hæmoglobin were both reduced in quantity. Arsenic had not been well borne, but some improvement had been noted after the exhibition of dialysed iron.

Dr. G. A. SUTHERLAND showed an unusual case of Rickets in a child aged three years.—Mr. JACKSON CLARKE took part in the discussion.

Mr. C. MANSELL MOULLIN showed a case of Phelps' Operation for Inveterate Talipes; one of Laminectomy for Intra-spinal Caseous Abscess pressing upon the anterior columns of the cord; and a third of Meyer's Operation for Carcinoma of the Breast. Mr. Mansell Moullin pointed out the exceedingly unsatisfactory position of the operation for removal of the breast as performed at present, stating that nearly every surgeon admitted at least 60 per cent. of local recurrences (as distinguished from metastatic deposits and

regional recurrences), and many of them an even higher proportion. Meyer's and Halstead's operations aimed at a much more thorough removal; the skin was excised very widely, without regard to apposition when the operation was completed; the whole of the axillary and infra-clavicular spaces were cleared, both pectorals were excised, and the whole of the mass removed was taken away *en bloc* without the growth being touched or even approached, so that there was no risk of cancer dissemination during the operation. The operation took but a very little longer than the ordinary one; there was practically no hæmorrhage and but very little shock. Unfortunately Halstead's statistics were useless, as only two out of his fifty cases were of three years' duration. Volkmann, however, who admitted 60 per cent. of local recurrences in his ordinary cases, had performed a somewhat similar operation (removing the pectorals &c.) in thirty-eight especially bad cases with a local recurrence in only 35 per cent. Mr. Mansell Moullin pointed out that it was practically impossible to remove the fascia covering the pectoral muscle (and with it the lymphatics running upwards from the carcinomatous deposit) without removing the whole of the muscle; and to this free removal must be attributed the much higher percentage of success attained. The arm, it is true, was tied down to the side, but if the risk of local recurrence was reduced by 25 per cent. this was of little importance.—Mr. PEXTON BEALE thought that laminectomy should only be performed as a means of reaching some special part—for example, the posterior aspect of the body of a vertebra. If the surgeon was going to operate upon the body of a vertebra, the seat of tuberculous disease, it was certainly his duty to remove all the disease most thoroughly, and this would often involve the cutting through and removal or displacement of the whole or part of one or more laminae. If attempted, it should be done thoroughly, just as if tuberculous glands in the neck were to be removed they should be completely removed, and the necessary operation might be a serious one; but it was better to leave them alone than not to be thorough in their removal.—Mr. C. B. KEETLEY and Mr. JACKSON CLARKE also commented on these cases.

Dr. WILLIAM HILL showed a case of Tuberculous Disease of the Nose.—Dr. CLIFFORD BEALE called attention to the need of early diagnosis in cases of tubercle of the nose. The disease probably attacked from the surface and was amenable to treatment so long as it remained superficial, but became exceedingly resistant when infiltration of the deeper tissues had taken place.

ÆSCULAPIAN SOCIETY OF LONDON.

Exhibition of Case and Specimens.—Morbus Cordis.

A MEETING of this society was held on May 17th, Dr. A. G. BARTLEY, President, being in the chair.

Mr. STEPHEN PAGET showed: 1. A case of True Acute Arthritis of Infants in a child six months old. An acute abscess formed in the lower epiphyseal line of the femur and was opened at once. Though the joint had appeared involved the infant recovered with a freely movable joint. 2. A specimen from a somewhat similar case in a child two and a half years old with abscess in the upper epiphysis of the humerus, suppurative of the epiphyseal cartilage spreading to the shoulder-joint and requiring removal of the head of the humerus and of the upper end of the shaft, which was hollowed out and full of fungous granulations. The child did well after operation. 3. A specimen of Acute Tuberculous Disease of the Larynx in a man in whose case there was some difficulty in diagnosis, the fixity of the tongue suggesting cancer. The patient died from advanced pulmonary tubercle. The thyroid cartilage was necrosed, the epiglottis destroyed, and the greater part of the tongue was covered with a sloughing ulcer. The cervical glands were also infected.

Dr. A. HAIG read a paper on the Treatment of Morbus Cordis by Iodides and other Drugs which lower Blood Pressure. The principle underlying this treatment consists, as he showed, in strengthening the heart by relaxing the arterioles, and so reducing the arterial resistance with which it had to contend. The Schott system aimed at the same effect by using baths to relax the cutaneous vessels and exercise to relax those in the muscles.¹ A consequence of vascular dilatation in the cardiac muscle was, he observed,

the direct and increased nutrition of this organ. Tracings were shown illustrating the influence (1) of exercise, (2) of opium, and (3) of iodides upon cardiac action. The use of opium was objectionable on account of the rebound with contraction of arterioles which quickly followed relaxation. The same reaction, indeed, followed in the case of iodides, but much more slowly, and therefore gave little trouble, cardiac nutrition having improved meanwhile. Dr. Haig drew an important distinction between (a) heart failure due to mechanical lesion, which was best treated by digitalis and like remedies, and (b) failure on account of excess of work from contracted arterioles and high blood pressure. This state was often the precursor of Bright's disease; it was particularly benefited by vascular relaxants—e.g., iodides.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Quinine Poisoning.—Intestinal Obstruction.—Exhibition of Cases and Specimens.

A MEETING of this society was held on May 15th, Dr. J. S. TEW, President, being in the chair.

Mr. THRESIDDER showed two cases:—1. A woman aged forty afflicted with Diffuse Scleroderma, which involved the lower part of the face and neck, the forearms and hands, and the lower part of the legs and feet. The thickening exists in the true skin, so that it can with difficulty be caught between the finger and thumb; the surface is glossy. The joints of the hands and feet are deformed and their movements restricted. The extremities are also subject to attacks of blueness lasting about half an hour each and resembling Raynaud's disease. Nodules like those of rheumatism have from time to time appeared on various bony prominences. The symptoms from which the patient suffers are extreme debility and intermittent vomiting. The pathology of the disease is obscure, but in all probability is a tropho-neurosis. She has suffered from the disease for eighteen months. 2. A man aged forty-two on whom he had performed Nephrectomy for Calculous Abscess of the Kidney; the man had been twice operated on successfully for stone in the kidney.

Mr. KINGDON showed five cases: (1 and 2) a man aged fifty and his daughter aged eighteen, who suffered from Anterior Pyramidal Cataract; (3) a boy aged ten suffering from Hydrophthalmos; (4) a woman aged twenty-eight afflicted with Lupus of the Conjunctival Surface of the Upper Eyelid; and (5) a woman aged eighteen affected with Double Dermoid of Cornea.

Mr. WOOD described a case of Quinine Poisoning from a dose of forty grains. The symptoms were deafness, staggering gait, and giddiness, and much relief was obtained by the administration of an emetic.

Dr. MICHIE read notes of a case of Operation for Intestinal Obstruction in a man aged twenty-eight. Constipation was of long standing.¹ Finally there was no action of the bowels for fourteen days, and vomiting also supervened with some abdominal distension and visible peristalsis. Nothing was revealed by rectal examination. At the operation a growth was found in the splenic flexure of the colon and another in the remains of the urachus; a temporary artificial anus was made on the proximal side of the growth, as the patient's condition would not then admit of a prolonged operation. At a subsequent operation the growth was removed and the artificial anus closed, the patient making an excellent recovery. Dr. Michie had operated in all on thirteen cases of intestinal obstruction; ten recovered, though one died from recurrence of malignant disease.—Dr. Cattle, Mr. Tresidder, Dr. Hunter, and Mr. Wray spoke, and Dr. Michie replied.—Dr. MICHIE also showed the following pathological specimens: 1. The Portion of Intestine showing the Tumour removed from the case described. 2. Solid Ovarian Tumour. 3. Hydronephrotic Kidney. 4. Two Specimens of Vermiform Appendix removed by operation. All the cases recovered.

Mr. WILLIAMS showed specimens from a case of Double Hæmato-salpinx which had been successfully removed by operation. On one side the distended tube had ruptured into the space between the layers of the broad ligaments, the tumour being the size of a large cocoanut at the time of the operation.

¹ The kidney was shown, and also a large branched renal calculus from this case.

¹ Broadbent: Practitioner, May.

Reviews and Notices of Books.

Introduction to Physiological Psychology. By Dr. THEODOR ZIEHEN, Professor in Jena. Translated by C. C. VAN LIEW, Ph.D., and OTTO W. BEYER, Ph.D. Pp. 305. With twenty-one Illustrations. Second Edition, enlarged and improved. London: Swan Sonnenschein and Co. New York: Macmillan and Co. 1895.

It cannot be a matter of surprise that when the functions of the principal organs of the body had been subjected to scientific examination those of the brain and nervous system should be carefully scrutinised, and, although at first sight the operations of the mind do not seem to lend themselves to those methods of inquiry which have proved so valuable in the case of the kidney and urine and of the various glands that pour their secretions into the alimentary tract, yet it could not long be overlooked that the organs of sense were amenable to strictly physical methods of inquiry, and that, as the sensations which are the foundations of the mental faculties can be tested and modified in various ways, so the mental powers themselves can be indirectly made the subject of examination, and thus the products of the activity of the cerebro-spinal and sympathetic systems be brought under the same laws as those which are found to be in operation in other organs.

Professor Ziehen starts with the antithesis of material and psychical phenomena, but lays down as a proposition, which is fundamental for the entire field of physiological psychology, "that there are undoubtedly a certain number of psychical phenomena or processes that do not occur independently of, or without relation to, certain material phenomena and processes, but stand in obvious correlation to the latter," or, in other words, that certain concomitant material processes correspond to a certain series of psychical processes, so that the latter cannot occur without the former, or the former without the latter; and he instances in proof of this the fact that removal of the occipital lobe of the brain in the dog causes permanent and complete blindness. He proceeds to say that if we investigate the question as to whether such material processes in the central nervous system accompany all psychical phenomena the answer will be decidedly in the negative.

It is proper to observe that Professor Ziehen regards the terms "psychical" and "conscious" as, at the beginning of the inquiry at least, identical terms. He does not admit the possibility of an unconscious psychical process. The simplest nervous process is a reflex action, but, although these actions often exhibit certain coördinated and purposive characters, yet he maintains we know nothing of any psychical correlate for this reflex purpose, and so with motor reactions that are not the invariable result of a definite stimulus like reflex acts, but which are modified while in progress by the action of new intercurrent stimuli. These he calls "automatic acts" or "reactions," and holds that they are not psychical. He instances the pianist, who executes an often-practised piece of music whilst his thoughts are wandering elsewhere, and as another example the descent of a flight of stairs whilst in deep thought. But we imagine that in all such cases a psychical process, feeble, indeed, and to which the attention is but slightly directed, but still existing, is being carried on, though the higher faculties of the mind may be exercised in another direction.

The distinction between reflex and automatic actions is exemplified by Dr. Ziehen in the frog from which the cerebrum has been removed. Here, if the foot be pricked and a movement of retraction made to withdraw the foot from the stimulus a reflex action is performed; but if, in leaping, the animal avoids an obstacle placed in front of it by jumping to one side an automatic action is accomplished, which is still

entirely destitute of psychical significance, and differs but little from a reflex act. It will be seen how completely this explanation of the phenomena observed differs from George Lewes' doctrine that in the frog destitute of brain a certain psychical power remains in the rest of the nervous centres.

From the consideration of reflex and automatic acts Professor Ziehen proceeds to that of simple conscious acts, in which a psychical process is really involved, and endeavours to show that, apart from and outside of the chain of sensory stimulus, sensory centre, motor centre, and muscle which exist in reflex and automatic acts, and in which the acts performed are modified through the agency of external intercurrent stimuli, the motor act in conscious acts is modified by intercurrent mental images or is accompanied by psychical processes. This psychical process, he considers, consists of three chief factors: the sensation or perception, the play of motives or association of ideas—that is to say, deliberation—and, lastly, the action. Anatomically, it has been shown by Ramon y Cajal and others that as the sensory fibres ascend in the cord they give off collateral branches, by which the stimulus is transferred to motor elements, the lowermost of which terminate in the cord, and are thus subservient to reflex acts, whilst others go to some higher centre, as the sensory ganglia in the medulla oblongata or at the base of the brain, and minister to automatic or instinctive acts; whilst others, again, pass to the brain cells and thus constitute the paths by which conscious action is induced.

Several chapters are occupied in discussing the sensations aroused through the several senses and the modifications they present. In the sensations of touch, for example, Dr. Ziehen discriminates four classes: sensations of position, of active motion, passive motion, and of active touch, the last differing from passive touch in having a motor element in it. He then considers the time properties and the emotional tone of the sensations, and proceeds to the "association of ideas." The following quotation—in which *Ec* stands for central or cortical excitation, *Ei* for ideational excitation, and *El* for latent excitation—will give an idea of the author's style and mode of treatment of his subject. "The association of ideas," he says, "is accomplished by the use of two kinds of elements: new sensations are received from the external world, and the mental images of former sensations are already at hand in the cerebral cortex. These latent ideas are constantly called up in consciousness and associated with the new sensations. We see a dark cloud—i.e., a stimulation *Ec* (cloud)—has been transmitted from the retina to the sensory cells of the cerebral cortex. The psychical correlate of this material excitation of the cortex is the visual sensation of the dark cloud. A series of related ideas are connected with this sensation by association—for example, among others, the idea of rain. The material excitation *Ei* (rain) in the memory cells of the cortex corresponds to this idea of rain, which is associated with the visual sensation of the cloud. This material excitation *Ei* (rain) did not exist before; only the material disposition *El* (rain) was already at hand in the memory cells, where it had been deposited by one or more visual sensations of rain. Previous to its excitation no psychical process corresponded to this *Ei*; it was merely a material trace, a latent image of memory. Only after the association of ideas has changed *El* into *Ei* does a psychical phenomenon, the idea of rain, also appear as the correlation of *Ei*. In the same manner this one idea is followed by numerous others; latent images of memory are constantly called up above the threshold of consciousness, or, as it is often expressed, reproduced. It is just this process of reproduction that we designate as the association of ideas or ideation."

The nature of memory is discussed in one of the chapters, and the author regards it as another phase of the association of ideas. He considers that to recall the mental image of an

object or sensation it is necessary that the image of the object in memory must be intact, and that the association as such must take place normally, which does not seem to carry us much further than to say that memory is, as it were, memory. However, he refers to some interesting observations by Ebbinghaus, who endeavoured to estimate the influence of time on memory by arranging words in series of different lengths, but without regard to sense. After learning them he tested the degree to which, and rapidly with which, the memory failed in regard to them, and expressed these numerical relations in the following law: that "the quotients of the amounts retained, by the amounts forgotten, are to each other inversely as the logarithms of the various periods of time that have elapsed." It is more interesting to know that the verses of an epic poem can be ten times more easily retained than senseless series of syllables, and that in Ebbinghaus' case one reading was sufficient to fix in the memory a series of from seven to eight syllables, but that forty-four repetitions were necessary for a series of twenty-four syllables. There must be great differences in this respect, for Theodore Hook is stated to have remembered the names over all the shops in Oxford-street from the Circus to Tottenham-court-road after once walking down the street in question with that object in view.

The work is a suggestive one, and has been very well translated by Drs. van Liew and Beyer. An index would have added considerably to the value of the book.

An Introduction to Pathology and Morbid Anatomy. By T. HENRY GREEN, M.D., F.R.C.P., Physician and Soecial Lecturer on Clinical Medicine at Charing-cross Hospital and Physician to the Hospital for Consumption and Diseases of the Chest, Brompton. Eighth Edition. Revised and Enlarged by H. MONTAGUE MURRAY, M.D., F.R.C.P., Physician to Out-patients and Lecturer on Pathology and Morbid Anatomy at Charing-cross Hospital. Illustrated by 224 Engravings. London: Henry Renshaw. 1895. Price 17s.

To past generations of students Green's Pathology was so well known in the Renshaw's Manual Series that the black book in foolscap octavo with red edges is what first comes to the mind when a text-book of pathology is mentioned. As the subject grew, however, and more attention had necessarily to be paid to it, this little book had to be gradually enlarged, and under the editorship of Mr. Stanley Boyd it assumed much more formidable proportions. Now we are offered an eighth edition still further revised and enlarged by Dr. Montague Murray, who has, we may say at once, performed his editorial duties with great discretion and consequently with marked success. It is an exceedingly difficult matter for any editor to bring the work of another man well up to date without breaking the continuity of plan or without interfering with the general scheme, but Dr. Murray has been as successful as his predecessor in maintaining a continuity of idea and expression which cannot be too greatly praised, and in its present form we predict a success for Green's Pathology almost equal to that which it attained in its earlier editions. We think, however, that it would have been well if some of the old illustrations had been removed or replaced by drawings made from specimens prepared by more recent methods; we will only indicate in this connexion some of the drawings illustrating the section on cancer, but there are others to which the same remark applies. The new illustrations are, many of them, most admirable, those illustrating vegetable parasites and the nervous diseases, the section on which has been drawn up by Dr. Mott, being specially noticeable.

In these days of ponderous text-books Green's Pathology and Morbid Anatomy may be accepted with confidence by the student as containing a very good and accurate description

of the groundwork of the subject, and an excellent introduction to the larger treatises with which he may have ultimately to deal. The work is, of course, very considerably increased in size, but it is still a very handy, manageable volume.

Annual of the Universal Medical Sciences: a Yearly Report of the Progress of the General Sanitary Sciences throughout the World. Edited by CHARLES E. SAJOUS, M.D., and seventy Associate Editors, assisted by over 200 Editors, Collaborators, and Correspondents. Illustrated with Chromo-lithographs, Engravings, and Maps. Five Volumes. 1894. Philadelphia, New York, and Chicago: The F. A. Davis Company. London: F. J. Rebman.

MOST of the readers of THE LANCET are acquainted with this excellent and important work, to which we have year by year as the volumes appeared drawn attention in our columns, and to which we have frequently made reference when introducing a note on the latest contributions to subjects of special interest. There is no other work of reference with which we are acquainted which supplies the want so ably satisfied by this annual. The important papers written during the previous year are epitomised, the cases of interest mentioned, new inventions or discoveries in every branch are placed in their right position as regards others of similar character, the action of remedies, new or old, is carefully noted, &c.

The first volume deals with the diseases of the lungs and pleura; of the heart and pericardium; of the stomach, pancreas, and liver; with diseases of the intestines and peritoneum, and with cholera; with animal parasites; the kidneys and bladder, and with diabetes, &c.; with fevers; diphtheria, croup, pertussis, parotitis, scarlet fever, measles, varicella, and röteln; with rheumatism and gout; and with diseases of the blood and spleen. Possibly the most interesting parts are that dealing with fevers and the one which treats of the diseases of the intestines and peritoneum; in the latter there is a section in which the experience of physicians in Russia and other parts in dealing with cholera by various remedies is summarised, and statistics of the results obtained by different observers are given.

The second volume treats of the following subjects: diseases of the brain and spinal cord; peripheral nerve diseases; mental diseases; inebriety and morphinism &c.; diseases of the uterus, ovaries, and tubes; menstruation; diseases of the vagina and external genitals; diseases of pregnancy; obstetrics; diseases of the new-born; dietetics and the digestive disorders of infancy. The editor specially draws attention to the sections which treat of the diseases of the brain and spinal cord and of the uterus and adnexa.

The third volume treats of surgical subjects—the surgery of the brain, spinal cord, and nerves; of the thorax; of the abdomen; of hernia; of the rectum and anus; of the genito-urinary apparatus in the male; of syphilis; of deformities; of amputations, excisions, and plastic operations; of fractures and dislocations; of diseases and injuries of arteries and veins; of oral and facial surgery; of surgical mycosis; of surgical diseases; of traumatic neuroses; of surgical dressings and antiseptics; and of anaesthetics. This volume more than any other brings before the reader the amount of work done during a twelvemonth, and conveys some impression of the advance which is being continually made in this department of our art.

The fourth volume contains the sections on diseases of the skin; ophthalmology; otology; diseases of the nasal cavities, naso-pharynx, pharynx, larynx, trachea, and cesophagus; intubation of the larynx; diseases of the thyroid gland; legal medicine and toxicology; medical demography; and bacteriology. The section which treats of ophthalmology is, perhaps, the most fully illustrated of any in the annual, and deals with the extensive literature of the subject in a very

complete manner. This section occupies no fewer than 168 pages.

The sections in volume five are devoted to the following subjects: general therapeutics and pharmaceutical chemistry; experimental therapeutics; electro-therapeutics; gynaecological electro-therapeutics; climatology, balneology, and hydrotherapy; hygiene and epidemiology; anatomy; anomalies and monstrosities; physiology and biology; histology; and microscopical technology. In this volume the article to which attention is especially directed is the one on general therapeutics.

A feature of great importance in a work of the magnitude of this annual is the accuracy and fulness of the index; here the general index at the end of the last volume is full and satisfactory. It is arranged in parallel columns, "general index," "therapeutics," and "authors quoted," and reflects great credit on those responsible for it, Dr. D. Braden Kyle of Philadelphia, and M. Eugène Devereux, A.M., and Madame N. J. Devereux of Paris. After the general index comes a reference list of journals 1153 in number, and books, monographs, theses, &c. to the number of 176. We should mention that there is also an index to each volume prepared by Madame N. J. Devereux.

New Inventions.

A SIMPLE URETHROTOME OR URETHRAL KNIFE.

I HAVE long been impressed with the inaccurate way the little operation of meatotomy is performed, and no one can deny the equally inaccurate way in which its more important

congener, internal urethrotomy, is done in spite of the multiplicity of contrivances invented. Meatotomy is nearly always underdone or overdone, sometimes merging into hypospadias in the latter case. These and other defects are owing to the absence of really scientifically constructed mechanisms capable of allowing varying adjustments and of making certain defined incisions in regions out of sight and touch. The urethrotome is a blind, expensive, and too often a disastrous tool, transforming the urethra into a zig-zag pocketed route instead of affording a capability of restoring a normal axis and calibre to this canal. Hence, owing to this and to the unpleasant sequelæ which often result, many surgeons now adopt external division as a more satisfactory expedient. If, however, we lay down a rule—viz., "confine incisions to stricture tissue, and to where it is most abundant, and follow up by dilatation by means of the gentle use of tapering sounds"—I think internal division would not be open to the objections laid to its charge. I beg to offer to the notice of the profession in the present instance the instrument herein figured—and which has been excellently made for me by Messrs. Arnold and Sons, London—for the performance of meatotomy and the division of certain penile strictures. It cuts only at B.C. It is blunt at A, and so it slides over the mucous membrane until the stricture is met, which it cuts with the edge, B.C. Hence it cuts flush with the mucous membrane, and that is the chief advantage claimed, the seat and site of the coarctation being first determined by a bougie demi-boule. On another occasion I hope to offer a modification of this knife, for the division of deep strictures, fitted with a guard which, by rising any desired extent from the blade, can ensure any desired incision as regards depth and direction.

Finsbury-pavement, E.C.

JAMES MACMUNN.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the committee of the Association of Fellows of the Royal College of Surgeons of England was held at 5.30 P.M. on Wednesday, May 22nd, 1895, at 25, Grosvenor-street, W. Dr. Robert Barnes took the chair in the unavoidable absence of the President, Mr. George Pollock, and there was a large attendance of members. The minutes of the last meeting of the committee were read and confirmed. The following letter was read by the Honorary Secretary (Mr. H. Percy Dunn):—

"10, Old Burlington-street, Feb. 27th, 1895.

"DEAR SIR.—On behalf of Mrs. John Whitaker Hulke, who is too unwell to attend to any correspondence, I beg that you will tender to the committee of the Association of Fellows of the Royal College of Surgeons her most grateful thanks for the kind resolution of sympathy forwarded to her on the occasion of Mr. Hulke's death. I need scarcely say that such marks of esteem for him are greatly appreciated by Mrs. Hulke.

"I am, dear Sir, gratefully yours,

"EDWARD W. WILMOT.

"H. Percy Dunn, Esq., 52, Wimpole-street, W."

A letter was also read from the Secretary of the Royal College of Surgeons of England acknowledging the receipt of a copy of the resolution of sympathy upon the death of Mr. Hulke, as President of the College, and conveying the announcement that the resolution would be laid before the Council at its next meeting; and the Honorary Secretary reported that the resolution had been acknowledged with the thanks of the Council (on March 7th). The Honorary Secretary called attention to the fact that a new President of the Royal College of Surgeons of England had been appointed in succession to Mr. Hulke, and pointed out that the time had now come for the subcommittee appointed at the last meeting in reference to proposed alterations in the charters and by-laws to begin its work. Thereupon a resolution was passed that the subcommittee should be summoned to meet on the 28th inst. at 101, Harley-street, to determine the points which should be pressed upon the Council of the College by the subcommittee acting as a deputation to the committee of the Council.

The Honorary Secretary having reported that there would be five vacancies on the Council of the College to be filled on Thursday, July 4th, the committee proceeded to consider the names of Fellows who should be invited to represent the views of the Association at the election. After some discussion it was unanimously resolved that Mr. A. T. Norton, Mr. Victor Horsley, and Dr. Ward Cousins should be invited to come forward as the candidates of the Association, Mr. A. T. Norton, who was present, accepted with thanks the nomination of the committee, and the Honorary Secretary was instructed to communicate with Mr. Horsley and Dr. Ward Cousins.

It was understood that of the three retiring members of the Council of the College—viz., Sir Spencer Wells, Mr. J. Hutchinson, and Mr. Alfred Willett—only Mr. Willett was likely to offer himself for re-election, and it was decided that the committee should recommend the members of the Association to support his candidature.

A vote of thanks to Dr. Barnes for presiding terminated the proceedings.

INVERNESS MEDICAL SOCIETY.—At the last meeting of the Inverness Medical Society the question of medical clubs and medical aid societies came up for discussion. There was a full attendance of members, and the general opinion of those present was that the salaries paid to the medical officers of medical clubs and friendly societies were quite inadequate to the amount of work performed. The conclusions arrived at by the meeting are embodied in the following resolutions, which were carried unanimously:—1. That all candidates for admission to any friendly society, medical club, or any other medical benefit society be charged an examination fee of 2s. 6d. whether "passed" or not. Such fee to be paid by the society. 2. No "married members'" branch to be countenanced on any terms. 3. That 2s. 6d. per head per annum be the minimum sum paid to the medical officer for attendance on members of these societies. This not to include medicines.

THE LANCET.

LONDON: SATURDAY, JUNE 1, 1895.

THE full interest of a meeting of the General Medical Council is rarely developed in the first two days of the session. But enough has already taken place to enable us to say that the present session—the fifty eighth—will not compare unfavourably in this respect with its predecessors. It is undeniable that of late years there has been more life in the Council, and that it has been more in touch with the profession than in the anterior period. We believe this to be the case and to be a considerable part of the justification of the Act of 1886.

The first event of consequence of course in any session is the opening address of the President. A great deal depends on this. To take a metaphor from the orchestra, he is responsible for the reading of the piece. He shapes the estimate of the proportion of subjects, and he can often contrive to give a turn to the course of business. It is but mere justice to Sir RICHARD QUAIN to recognise that his opening addresses have been intrinsically interesting as *résumés* of the history of the subjects with which the Council has to deal. It is inevitable that the proclivities of the President himself should appear in these addresses. On the present occasion there is no concealment of the fact that the coming edition of the Pharmacopœia is the subject which engrosses the most of the President's attention. If Sir RICHARD QUAIN shows himself a little conservative in regard to the conditions of editorship and preparation, it is impossible to deny that he speaks with a rare experience and a large responsibility. The question of any changes in these arrangements is undoubtedly important, and will be dealt with by the Pharmacopœia Committee, which has been already appointed. It is undoubtedly expected that the new Pharmacopœia will mark a step in advance of the present one. But it must be conceded that the present volume, with the addendum, has creditably sustained its place in the estimation of both practitioners and pharmacists of the three divisions of the Kingdom. It is easy to find fault with it—to show that it has left undone that which it ought to have done, and in particular has done that which it ought not, but, as a whole, it is a creditable starting-point for a new edition. We trust that the editorial arrangements in the entertainment of new drugs will carefully avoid both errors—"raw haste" and undue delay. This does not imply any very great change in the aspect of the book, but it may imply a great advance in its utility and may place it in a much more favourable position as respects the rival volumes which enterprising druggists publish as amateur performances in the nature of pharmacopœias.

The subject which at the moment at which we write figures most largely in the proceedings of the Council is that of the Registration of Midwives Bill. The minutes of the first day's meeting have an appendix consisting of communications to the Council in regard to certificates issued to and the registra-

tion of midwives, extending over twenty-seven pages, from all sorts of interested parties—*vis.*, one from certain Fellows of the Obstetrical Society, one from the Lancashire and Cheshire Branch of the British Medical Association, one from certain members of the Lancashire and Cheshire Branch of the British Medical Association, one from certain practitioners in Liverpool, one from the Midwives' Institute, one from the Workhouse Infirmary Nursing Association, one from the parish of St. Mary Abbots Kensington, one from the Ladies' Charity and Lying-in Hospital, one from St. Mary's Hospital Manchester, and one from the Association for Promoting the Compulsory Registration of Midwives. Two of these are unfavourable to the certification—or, rather, to the registration—of midwives as such. The rest are very much in favour of such steps and of legislation to enforce them. But if the majority of the communications to the Council are in favour of some way of certifying or registering midwives, the quality of energy and activity of protest seems to be possessed most largely by those who object to any such measures. On Wednesday a large part of the afternoon was taken up by a deputation of fourteen gentlemen who offered the most uncompromising opposition to the recognition of the midwife as such. The spokesmen of these gentlemen were Mr. COLIN CAMPBELL, Dr. HELME, and Dr. WOODCOCK. They described in powerful terms the evils of a little knowledge in midwifery. Whether they succeeded in convincing the Council that the little more knowledge possessed by the women of a few months' training, as compared with that of the woman who has had absolutely no training, constitutes any real danger to the community is another matter. They certainly stated their views in a dignified way. The Council very properly contented itself with merely hearing their statements, reserving all judgment on the matter till it has received a report from its own committee, appointed long since to watch any Parliamentary Bills on this subject, and now busily engaged in examining the Bill of Lord BALFOUR OF BURLEIGH. A great tactical error was committed by a section of the Council representing the extreme views as regards midwives in trying to snatch a premature victory by committing the Council to hasty resumption of the controversy with the Obstetrical Society with regard to the form of its certificate to midwives. This controversy, as we had all along anticipated, has been brought to an end by the Obstetrical Society adopting a form of certificate approved by the Executive Committee to which the Council relegated its functions in the matter. But a minority of the Council tried to reopen the controversy and throw on the President and his colleagues on the Executive Committee the ungracious duty of reopening the negotiations and obliging the Obstetrical Society to exchange the words "Examination in midwifery" for "Examination in midwifery nursing." This was, we think, an error of policy, considering that the whole subject is under the examination of a Committee of the Council, and the Council showed its sense of this by rejecting the proposal by a very large majority.

An important piece of business has been settled by the Council at its present meeting—the purchase of the property which includes the present premises, 299, Oxford-street and also 16, Hanover-square. The financial terms are

favourable. The money needed—not to exceed £20,000—including alterations and the purchase of the lease, will be advanced by the English Branch Council to the General Council at the rate of three per cent. There seems little prospect of the Council finishing its business before the Monday or Tuesday of next week.

WE should imagine that the result of the division last week upon Sir JOSEPH PEASE'S resolution regarding the Royal Commission on Opium could not have given rise to any surprise; the surprise would, indeed, have been great had he succeeded in carrying it. As it was, the resolution was negatived by a majority of 117 in a small house of 235, where we may be sure the anti-opium party mustered as strongly as they could. Mr. FOWLER had little difficulty in replying most effectively to Sir J. PEASE, whose speech involved an unprecedented personal attack on the members of the Royal Commission. The composition of that Commission apparently received the approval of even the anti-opium party, every witness offered by the Anti-Opium Society was heard, the investigation was of an exhaustive character—the Commissioners examined altogether over 700 witnesses,—and the weight of the evidence taken was such as to leave no reasonable doubt in the minds of unprejudiced people that the Commissioners were fully justified in making the report they did. The Commissioners were practically unanimous, for eight out of nine of their number signed the Report; and we think it is much to be regretted that Mr. WILSON, the dissident, did not submit his criticisms or suggestions for the consideration of his colleagues. We cannot be surprised that Mr. FOWLER indignantly repudiated the utterly ridiculous suggestion that because the Commissioners had accepted the hospitality which is proffered to everyone, and which it would have been churlish to have refused, they had thereby lost their character for impartiality. Mr. FOWLER deserves great credit, too, for his honesty and courage in going to the root of the subject. We do not go to India in this matter with clean hands. Whilst this wealthy country raises a revenue of from thirty to forty millions from drink it is not in a position to ask a poor country like India to give up its revenue from opium. The prevalence of the use of opium is partly attributable to the universal tendency among mankind to take some form of stimulant with which to comfort or distract themselves, and partly to a popular belief in its efficacy as a domestic medicine. The misery, disease, and crime connected with the abuse of alcohol in Europe are infinitely greater and more common than the evils resulting from the abuse of opium in the East. As regards China, we believe that only about one-fifth of the total amount of opium consumed in that country is obtained from India, and it is perfectly true that if China did not get this amount from India she would supply herself. We do not say, of course, that a Government is any more justified than an individual would be in acting immorally because its action in this respect happens to be of limited extent; but it would surely be little short of criminal to make a vain attempt to remove one evil at the risk of introducing another and far worse one. There are several other considerations also, and Mr. FOWLER was quite

right in declaring that the Government objected to Sir J. PEASE'S motion because it involved a flagrant injustice on the one hand and was impracticable on the other, and because it would seriously menace our relations with the friendly States, with whom it was our duty to be upon the most friendly terms. As to excessive consumption [of opium causing harm there is no difference of opinion, but the use of opium in India is a moderate one, and there is no evidence of extensive moral or physical degradation from its use. Opium smoking is little practised in that country at any rate, and is considered a disreputable habit. The fact is that the anti-opium party had altogether overstated their case, and a variety of exaggerated and sensational statements have been made which have not been substantiated by the evidence that has been adduced. They consequently now find themselves in the unpleasant position of contemplating a pricked bladder. We hold no brief for the Indian or any other Government, and it is no part of our duty to support their officials as such; but we cannot help seeing that whilst so many of our countrymen in India have been doing all they can to strengthen the empire abroad by their courage and character for justice there are a number of people in this country who, if their counsel were followed, would do a great deal to weaken if not destroy it. There are several physiological and medical points referred to in the voluminous published evidence and in the Report of the Royal Commissioners, and more especially in Sir WILLIAM ROBERTS' memorandum, with which we may subsequently deal.

IN a few weeks' time the Fellows of the Royal College of Surgeons of England will once more be called upon to exercise their privilege of electing representatives to serve upon the Council of the College. This year the election of councillors will be invested with more than ordinary importance, for there will be no less than five seats to be filled, four of the five seats being absolute vacancies. Moreover, the election will in all probability be held under an amended by-law, and if this be so, voting papers will be sent unasked to every Fellow of the College in the United Kingdom whose address is known, and the number of Fellows voting ought to be largely augmented. These circumstances are bound to exercise a healthy and stimulating effect upon the Fellows, and many of them, formerly apathetic or indifferent, will doubtless begin to evince an intelligent interest in the affairs of the great professional institution whose destinies it is in their power to direct and control. With a view, therefore, of assisting the Fellows generally in their deliberations upon the constitutional questions which have been frequently discussed in THE LANCET, and which the Association of Fellows and the Society of Fellows have pressed or are likely to press upon the attention of the Council, we propose during the time that remains before the election to define the exact position of collegiate politics in a short series of leading articles. These we begin to-day by considering the position between the Council and the Fellows in particular relation to the work of the Association of Fellows.

Eleven years ago a revision of the Charters and by-laws

of the College was undertaken by the Council of the College, and the proposals of the Council were submitted to several meetings of the Fellows and Members held in the theatre of the College. At the very outset four resolutions were adopted by the Fellows and Members affirming the necessity of investing the Fellows and Members with a larger share in the management of the College; the necessity of having an annual general meeting of Fellows and Members for the reception, discussion, and adoption of a report from the Council; the necessity of submitting any change in the constitution or external relations of the College to the Fellows and Members for approval; and the desirability of conferring upon the Fellows of the College the privilege of electing the President of the College. These four cardinal points, which were proposed by Mr. PAUL SWAIN, with the cordial approval of the present President of the College, became the charter of the Association of Fellows, which then sprang into existence simultaneously with the late Association of Members. The Association of Fellows worked indefatigably to obtain material alterations in the Charters and by-laws for the purpose of conferring upon the Fellows greater influence over the administration of the affairs of the College; and though several of the more important proposals for the revision of the constitution were rejected by the Council, these concessions were secured:—1. The appointment of scrutineers to take the ballot at the election of the Council. 2. The discontinuance of the payment of a fee at election by members of the Council and by members of the Court of Examiners. 3. The appointment of a treasurer and the auditing of the accounts by a professional auditor. 4. The holding of an annual general meeting of Fellows and Members, at which a report from the Council should be presented and discussed. 5. The suspension of the confirmed minutes in the hall of the College for the inspection of the Fellows and Members. 6. The holding of meetings by direction of the President or Council or on a requisition signed by thirty Fellows or Members. 7. The reduction of the number of signatures required for nomination of candidates for the Council from six to three. These concessions were obtained after repeated applications and deputations to the Council. One only was embodied in the Charter of 1888, three were effected through amendment of by-laws, and the rest depend for their continuance on the good pleasure of the Council. One of the most important of these concessions—that granting the annual general meeting of Fellows and Members—may at any moment be suspended or abolished by the Council. This surely ought not so to be. When the Charter of 1888 had been obtained the Council of the College strongly urged the Fellows and Members to “rest and be thankful,” and it required steady perseverance as well as much dissemination of information among the constituency upon the true points at issue—information which we took every care should be clear, impersonal, and impartial—to secure further privileges for the Fellows. In 1890 a common room was assigned for the use of the Fellows and Members. Then followed meetings of the Fellows twice a year, separately from the Members, after counsel’s opinion had been obtained through the agency of a deputation of the Association of Fellows. The separate meetings of Fellows,

though established only by resolution of the Council, and not resting, as they should do, on a provision in the Charter, are capable of being made a great instrument for good in the life of the College. To this concession has at length been added such a simplification in the mode of distribution and collection of voting papers as will ensure the record of a larger number of votes by Fellows of the College at the election of councillors, and will make it the fault of the Fellows themselves if they abstain from interesting themselves in the administrative work of the College.

A further series of recommendations, which was formulated by the Association of Fellows more than a year ago and submitted to the Council, will be pressed forward by a deputation of the Association to the Committee of the Council appointed a few months ago to receive deputations from the Fellows. The following comprised the main points:—

1. That it should be lawful for the Fellows in meeting assembled to appoint an annual committee or other committees to consider and report on subjects referred to them, and to confer when necessary with the Council of the College.
2. That the President of the College shall be elected by the Fellows from among the past or present members of the Council at the meeting of Fellows in July.
3. That no alteration in the constitution and external relations of the College shall be effected without the consent of the Fellows convened to discuss such alteration.
4. That the term of office of members of the Council shall be six years instead of eight (making four vacancies instead of three annually), and that the system of substitute members be abolished.
5. That members of the Council shall not be eligible for re-election after serving for two consecutive periods of six years.
6. That the Council shall have power to increase the number of the members of the Court of Examiners from ten (as now limited) to any number not exceeding twenty.
7. That the meetings of the Fellows, the election of the President by the Fellows, the six years’ term of office of members of the Council, and the annual meeting of the Fellows and Members for the reception and discussion of the report of the Council shall be provided for in a new Charter, and that the conduct of the meetings at the College and other matters referred to in the above recommendations shall be regulated by by-laws. It will be seen from this programme that the Association is unflagging in its efforts, but we defer, for the present, consideration of the points raised.

Annotations.

“Ne quid nimis.”

THE BIRTHDAY HONOURS.

THE honour lists gazetted on the two preceding anniversaries of Her Majesty’s birth had led us to hope that the services which the medical profession render to humanity were to be recognised in the future to a greater degree than they had been in the past. It would seem, however, that these hopes are not to be realised, for the list of honours issued on the occasion of the Queen’s seventy-sixth birthday contains the names of but three gentlemen who also find a place in the Medical Register of the United Kingdom—Dr. Joseph Ewart of Brighton, Director-General James Nicholas Dick, C.B., and Dr. Salvatore Pisani. We trust, however, that the time is not far distant when a profession

which can furnish men who make themselves conspicuous by their bravery in defending a fort in the wild hills of the Pamira, who show their tact and ability to govern a province in South Africa, or, to come nearer home, do their best to keep England from epidemics like cholera, will be recognised by a grateful country. Sir Joseph Ewart, who has received the honour of knighthood, has rendered excellent service both to his country and to his profession and is a worthy recipient of the honour which has been conferred upon him. About the year 1852 he went to India where his important investigations into the sanitary condition of that country were rewarded with the highest medical post which the Government could bestow upon him. The records he prepared on the subject still remain a monument to his industry and ability. A considerable part of his life was spent in the service of the East India Company, and he was in medical charge of the Meywar Bheel Corps at Kherwarra during the time of the Indian Mutiny. His services to promote the health, wealth, and prosperity of Brighton, the town in which he resides, have been recognised by his grateful townsmen by their thrice returning him as Mayor of the borough, and he has just been chosen as a candidate to contest the representation of the borough in Parliament. Sir James Nicholas Dick, C.B., is the Director-General of the Medical Department of the Royal Navy, and his promotion to Knight Commander of the Most Honourable Order to which he belongs is well deserved. We have further alluded to the honour bestowed upon him under the heading of "The Services." Mr. William Hales Hingston, M.D., of Montreal has been made a Knight, and Mr. John Christian Schultz, M.D., LL.D., late Lieutenant-Governor of the Province of Manitoba, has been made a Knight Commander of the Order of St. Michael and St. George. The chief medical officer in the island of Malta, Mr. Salvatore Pisani, M.D., receives a Companionship of the same Order.

HYDROPHOBIA IN YORKSHIRE.

RABIES in dogs still prevails in its old haunts in Lancashire and Yorkshire, though it is present in other parts of England and also in Ireland. It is no wonder, therefore, that cases of persons who have been wounded by really rabid or suspected dogs, and who have been hurried off to Paris to undergo preventive inoculation, are frequently recorded; while a death from mad dog-bite is now and again brought under our notice. The most recent of these fatal accidents occurred quite lately, and according to the report received it presents some rather unusual, though not by any means novel, and instructive features; and it is also the more painfully noteworthy from the fact that the victim was brother of Mr. Nunneley, senior surgeon of the Leeds Infirmary. From the evidence given at the coroner's inquest, held at that institution on May 20th, it seems that the deceased was bitten or scratched by a dog towards the end of last December, though the injury was so slight that no importance was attached to it. Early in January the animal was ill, and on being examined by a veterinary surgeon was found to be "out of sorts," and it is stated that no symptoms of rabies were present, yet for some reason or other it was considered advisable to have it destroyed, perhaps because it had the reputation of being naturally savage, though this is not, we believe, a characteristic of its breed—the dachshund. Mr. Nunneley (the victim) cut one of his hands with a piece of glass in March, but the wound was neglected and tedious in healing, and lately there was some pain in the cicatrix remaining. Two days before his death he complained to his brother of being unwell, the chief symptoms being slight difficulty in breathing and swallowing; on the following day he was much worse, and died in the evening. The medical

witnesses were of opinion, from the symptoms, that death was due to hydrophobia, though they considered the latent period between the infliction of the injury and the manifestation of the malady to be much longer than is usually the case. The veterinary surgeon stated that the dog, though it showed no symptoms of rabies, was savage, and a necropsy revealed no indications of that disease. The deceased was inoculated in Headingley, and on May 20th a dog suffering from rabies was brought from that place to the surgery of this veterinary surgeon in Leeds; it was said to have bitten a person some time ago. The points to be noted in the above painful case are the very trifling nature of the injury by which the rabific virus found admission to the circulation, the apparent freedom of the dog from rabies, and the rapidity with which death took place after the symptoms set in. Had rabies been suspected in the dog it should have been kept alive until its condition was ascertained—adopting all possible precautions against its doing damage, of course; and a very brief time would have settled the question, as rabid dogs live only a few days after the symptoms are developed. The prolonged latency is, of course, another matter to be noticed, though it is not at all infrequent, and many instances are to be found in which it has been much more protracted. It is greatly to be desired that more energetic and effective measures should be taken to suppress this most distressing and awe-inspiring disease of man and beast in the United Kingdom; for with the present measures, as has been so often insisted upon, we shall never succeed in getting rid of it, and such cases as the one now noticed will inevitably occur. Human life may not, in the opinion of some people, be of so much value pecuniarily as that of animals, but here we have both at stake, and this might induce the Board of Agriculture to have recourse to similar measures to those adopted for the stamping out of, say, the contagious pleuro-pneumonia of cattle, a disease that could not be transmitted to mankind, and yet was got rid of, though at an enormous expense in money and great public inconvenience.

AMYOTROPHIC LATERAL SCLEROSIS.

IN the spring number of *Brain* Dr. Mott publishes a very full account, both clinical and pathological, of a case of this disease. When Dr. Charcot first directed attention to the subject he described this as a deuteropathic form of progressive muscular atrophy, meaning by this name that he regarded the affection of the motor cells on which the muscular wasting depended as a secondary result of the sclerosis which was present in the pyramidal tracts. In this country and in Germany, however, some of the leading observers, and more especially Dr. Gowers, insisted that the difference between this and progressive muscular atrophy was only one of degree, and that in all cases of progressive muscular atrophy there was sclerosis of the pyramidal tracts. It is quite conceivable that in certain cases the sclerosis in the pyramidal tracts may be so slight as not to show itself in the usual clinical phenomena of lateral sclerosis, while in others it may be so extensive and so severe that even the muscular atrophy which is present fails to mask it, and so, in addition to the wasting of muscles, we have in such a case the spasticity and exaggerated reflexes which are characteristic of lateral sclerosis. Dr. Mott's case is interesting because of its completeness, and more particularly because of the very exhaustive and careful microscopic examination which he has carried out. The patient was a woman aged thirty-nine who for five months before her admission to hospital had been troubled with a feeling of cold in the right leg and a sense of weight in walking. The weakness gradually increased, affecting also the right arm and later the left leg, and after that the left

arm. Very great wasting of the muscles of the limbs accompanied the weakness, the deep reflexes were all exaggerated, the sphincters were unaffected, and there was no sensory impairment anywhere. The wasting increased, the thoracic muscles became paralysed, bulbar symptoms were superadded, and the patient died rather more than a year after the onset of her symptoms. At the necropsy no distinct naked-eye changes were noted in the central nervous system except the wasting of the central convolutions of the brain. On microscopic examination of these convolutions numbers of granulation corpuscles were found, while sections in the occipital lobes failed to reveal any. Many nerve fibres were also noticed to have disappeared, and the large pyramidal cells were absent. Degenerated fibres were also found in the internal capsule, in the crus cerebri and the pons, and in the pyramidal system of fibres, and the pyramids and pyramidal tracts in the medulla and cord were much degenerated. The cells of the hypoglossal, the lower facial, and the spinal accessory nuclei were also found to be affected, and some had disappeared. In the spinal cord, besides the sclerosis in the pyramidal tracts, crossed and direct, already alluded to, the anterior horns were atrophied, and the anterior and internal groups of cells had disappeared in the cervical region. In the dorsal cord also the anterior horns were atrophied, but Clarke's column was unaffected. In the lumbo-sacral cord likewise the anterior horns were atrophied, and the wasting and degeneration of cells affected chiefly the anterior and internal groups of cells. The anterior roots and the peripheral nerves showed numerous degenerated fibres, while the posterior roots were unchanged. It will thus be seen that the whole motor tract showed signs of degeneration, and Dr. Mott expresses the opinion that a simultaneous degeneration of the upper and lower segments of the motor path took place, a view which he thinks is justified by the clinical history, as well as by a study of the manner in which the different parts of the nervous system were affected. If the disease depended upon a chronic inflammation it is not easy to conceive any reason for its limitation to certain groups of cells in the cord and the complete escape of Clarke's column. If, however, it is regarded as a degenerative process affecting the motor path, the course of the disease not only in this case, but in others widely different, is explained. If, for example, the incidence of the degeneration is chiefly on the lower segment, the symptoms of progressive muscular wasting will be more obvious; while, if the incidence is mainly on the higher segment, then the symptoms of spasticity will be very evident, and the case will answer more to the descriptive term "amyotrophic lateral sclerosis." We congratulate Dr. Mott upon the care and skill with which he has examined a very interesting case, and upon the light which, by means of its study, he has been able to throw upon one of the numerous vexed questions of neurology.

THE PREVENTION OF OVERLAYING.

THE deaths of two more children smothered in bed formed the subject of an investigation last week in the Liverpool coroner's court. A singular fact observed in connexion with both of these cases was the recurrence of this apparent accident in two families a second and a third time respectively. In the circumstances it was natural and right that the coroner's jury should return an open verdict, at the same time severely censuring the careless parents. The question of motive, however much we may wish to exclude it, cannot be entirely omitted in dealing with cases of this kind. Let us grant that they are, for the most part, of accidental causation, and still the mere fact that some hundreds of infants are annually suffocated by overlaying in London alone is enough to prove inexcusable neglect or mismanagement on the part of parents and the need of providing some

appropriate corrective. Repetitions of the same offence twice or oftener in one family argue thus much at least. The reprimand administered by the coroner and his jury will not fail, we hope, to impress once more on all who have the charge of infant children the absolute necessity of providing them with separate sleeping places. Law has of late years gone far to ensure the protection of children. It has made abundant provision against their being cruelly used, overworked, or systematically neglected. It has, nevertheless, been singularly apathetic as regards the danger of overlaying, to which infants are still constantly exposed. Surely this fact is enough to constitute a ground of intervention and to warrant the imposition of a sufficiently deterrent penalty.

FILTRATION AND FEVER.

A VERY important statement relating to the efficiency of the Pasteur-Chamberland filter in warding off water-borne diseases occurs in the report of the Minister of War recently presented to the President of the French Republic, and published in the *Journal Officiel* dated April 11th. It will be remembered that on the increase of typhoid fever in the French army some years ago measures were taken to ensure the purity of the water-supplies. That water used for drinking purposes was the origin of the disease had been clearly proved, and the remarkable reduction in the number of cases of typhoid fever since these steps were taken, which in the majority of instances consisted in the application of the Pasteur-Chamberland filter to existing supplies, affords ample confirmation upon this point. Thus, the contamination of the water-supply of Avesnes raised the number of cases from 2 to 3 per year to 105 in 1891; after the installation of Pasteur-Chamberland filters it was reduced to 1 in each of the three following years. The epidemic at Auxerre in 1862 attacked 129 men; these filters were installed and the number was reduced to 1 in 1893 and 1 in 1894. At Melun, where the water has always been polluted and is extremely bad, the number of cases in 1889 was 122, and since the application of this filter has fallen to 15, 6, 2, 7, and 7 respectively for the succeeding years. In the present year the filters were stopped through frost, and 28 of the cavalry who then drank unfiltered water were attacked with typhoid fever, while no case occurred among the infantry, who during this period drank only tea. The Cherbourg garrison had 110 cases in 1888 and 119 in 1889; these filters were installed in 1890, and the number of cases for the following years were 21, 8, 11, 3, and 3. At Dinan the annual average number of cases for the three years before Pasteur-Chamberland filters were supplied was 278, being in the following years 1, 2, 3, and 1. Typhoid fever existed constantly in the garrison of Lorient, the number of cases being 179 in 1888 and 171 in 1889. These filters were supplied during 1890, and the number of cases fell to 58 for that year and 2, 2, and 1 for the following years, rising in 1894 to 11 on the temporary use of an unfiltered water at that time considered pure, but subsequently condemned. Up to the present time typhoid fever has remained constantly present among the civil population, which was also attacked severely by the cholera epidemic of 1893; 1 case also occurred in the garrison, contracted by a soldier when visiting his mother, who had died from the disease. Absolutely identical results in the mitigation of typhoid fever by the adoption of these filters have been noted from year to year at Montpellier, where the number of cases was reduced from 391 to 49, and then to 14; at Perpignan, it was reduced from 131 and 197 to 18; at Blois, Vendôme, Lure, Auxonne, Vitry, Tulle, Clermont-Ferrand, Chambéry, Privas, Arignon, Toulon, Nice, Tarascon, Béziers, Lunel, and so on. Dealing with collective figures, in the 15th Corps a previous total of 1018 typhoid

fever cases has been reduced to 337; in the 12th Corps the number has fallen from 616 to 68; at Angoulême from 326 to 25; and in the 18th Corps from 292 in 1888 to 38. The total number of cases of typhoid fever in 1886 was 7771, since which year it has constantly and progressively fallen till in 1894 it was 3060. This interesting report concludes that the more the individual cases which occur are examined the more clearly it is shown that soldiers who possess in their barracks a pure water-supply are none the less exposed to the infection of typhoid fever in inns, public-houses, restaurants, and other public places which they have so many opportunities of frequenting. Thus at Nantes, where typhoid fever had formerly been reduced to isolated attacks, the majority of the 17 cases which occurred in 1893, and the 30 in 1894, were orderlies who took their meals at inns where the water was shown to be contaminated by infiltration of sewage from cesspools. The same thing occurred at Saint-Germain, La Flèche, Blois, Maubeuge, &c., and it may be taken as the best explanation of the sporadic cases which, occurring throughout an army of 450 000 men, are always found to make up a substantial total, and probably can never be altogether avoided. These results, which are obviously of an eminently practical and satisfactory kind, are of great interest, also, in that they are strikingly confirmatory of the experience which has always been furnished in the bacteriological laboratory in regard to the efficiency of this filter in removing pathogenic micro-organisms from water.

PLAGUE IN ATHENS, ENGLAND, AND HONG-KONG.

WE have received a most interesting report upon the epidemic of bubonic plague in Hong-Kong during the year 1894. Plague is perhaps the one disease of which we have an authentic description at periods of time coming down from 430 B.C. to mediæval times (1348), and so through the Great Plague of London (1665-66) to this last epidemic in 1894. The character of the disease seems not to have altered in any way since the time of Thucydides. The sudden invasion and the other symptoms, the buboes and hæmorrhages, are all as plainly marked in the Hong-Kong epidemic as they were in Athens 2500 years ago. There is one similarity between the epidemic at Athens and the plague of 1665 which we do not find mentioned in Dr. Lawson's report of the Hong-Kong epidemic, so perhaps the same conditions did not obtain—i.e., the absence of other diseases. Thucydides says the season had been healthy, and *ei δὲ τις προέκαμνε τι ἐς τοῦτο πάντα ἀπεκρίθη*. "If anyone were ill in any way all (those complaints) resulted in this (the plague);" while Boghurst in his description of the plague in London tells us "almost all other diseases turned into the plague." A great deal has been said of the heroism of the military in cleaning out and pulling down infected houses, and we would be the last to make little of their bravery; for to face an unknown danger and one invested with a nameless horror, as is the plague, to a non-professional mind is a far higher act of bravery than the facing other sorts of physical peril. Still, we think that the manful way in which the various medical officers, nurses, and hospital officials stuck to their work deserves no less recognition, although it was no more than their duty.

THAMES PORT SANITARY AUTHORITY.

THE Thames port is at present the scene of some of that steadily maintained public health work on which the freedom of this country from imported infection is so largely dependent. It is quietly and continuously carried out by day and by night, but it is only on special occasions that it is heard of and that it receives the recognition which it merits. During the last few weeks its usefulness has more than once

been prominently shown, as vessels have arrived in the Thames, which, after leaving the cholera-infected ports of South America, have had one or more attacks of that disease on board at some time during the voyage. Every such vessel is carefully examined by Dr. Collingridge or his deputy medical officer; the crew and passengers, if any, are examined; those who may be suffering from diarrhoeal symptoms of a suspicious type are temporarily removed to the port hospital at Denton; and such parts of the vessel as are deemed to need it, together with suspected articles, are disinfected. The vessel is then free to proceed up the river, enter dock, and discharge its cargo. This is a type of the work which has long been carried out by the port sanitary authority of London. It involves a considerable day and night staff, a hospital, steam launches, &c., and when it is remembered that the officers of the port authority of our metropolitan river have numberless other duties along both banks of the river, involving riparian districts in several counties, extending far up the river beyond the metropolis, and that they undertake all these duties without imposing any tax on the authorities and population abutting on the river, there can be no doubt that the services they render to London, and incidentally to the country, are deserving of public recognition and thanks. Again and again has the metropolis been saved from dangerous infection owing to the admirable organisation at the mouth of the Thames, and much the same may be hoped to occur again during any cholera prevalence this year, whether in one or other hemisphere or continent. Incidentally we may remark that the unity of London, which is now so much talked of, could hardly bring into being any improvement of this work; for the port sanitary authority of London not only takes in all the Thames waters within the metropolitan area, but extends the area of its action and jurisdiction far beyond. It begins at the Nore where the river is bounded by Kent and Essex, and includes the Middlesex and Surrey portions of the Thames to a considerable distance above the metropolis; and the whole service is not only efficiently performed, but is all paid for out of corporation funds. Londoners would here, at least, have nothing to gain by unification.

MEDICINE AND THE FINE ARTS.

M. ANDRÉ BROUILLET, the painter of the celebrated "Leçon Clinique," has completed another work with a medical motif. It is entitled "Un Coin du Pavillon de la Diphtérie à Trousseau" and comprises the portraits of several men whose names are household words throughout the entire civilised world. The following description of this masterpiece is from the facile pen of Dr. Marcel Baudouin, who was favoured with an early view:—"The scene is enveloped in the light of a fine autumn day, which throws into vigorous relief the forms of the personages represented. On an iron cot lies a chubby-cheeked, plump-limbed infant, while standing close at hand the *chef de service*, clad in working garb and wearing on his head the characteristic *calotte*, is in the act of injecting into the tissues of the small patient a whole syringe of the beneficent serum. The individual thus depicted is Dr. Molzard. Bending over the child we see the superintendent, Madame Gigot; and standing at the foot of the bed are MM. Chaillou and Martin. Finally, to the right, with his elbow resting on a small *étagère*, is Dr. Roux, clothed, like the others, in the classic white blouse. With an anxious eye he surveys the operation; but already the glimmerings of hope are perceptible in the expression of his eyes. When this scene was depicted the efficacy of the remedy had not been so fully tested as it has been since. The painting is blue in tone, and pervaded by that luminosity specially affected by the artist, who is not only an

able draughtsman but also a master colourist. His canvas without doubt will be the *clou* of the whole *Salon*, and we hasten to felicitate our friend and compatriot very sincerely." No doubt the skill of the artist fully merits the high eulogium passed by Dr. Baudouin; nevertheless, it may be questioned whether art is served by being employed as a method of depicting with painful realism scenes from the hospital ward. The public will be attracted to the picture neither on account of its artistic merits nor of its portraiture of eminent members of the medical profession, but on account of the fascination which such subjects always have for the curious. In this country it may be doubted whether the selection by an artist of subjects of this nature could possibly excite approval, and that a work of this class would ever be exhibited on the walls of Burlington House is in the highest degree improbable. But, whether owing to our insular prejudices or to a fundamental difference in taste, the British and French conceptions of art and its mission have never been quite the same. —

THE CHINO-JAPANESE WAR AND THE PRICE OF CAMPHOR.

JAPAN has refused to reconsider the cession of Formosa. The Chinese have been compelled to hand over the island to the Japanese, who have appointed a viceroy and will no doubt soon make their own arrangements with the native Malayan population. The *Spectator* adverts to a curious incident in connexion with this cession, which, it states, will directly affect every druggist and manufacturer of projectiles in Europe in consequence of camphor being produced only in Japan and Formosa, and of the use that is made of it in medical practice and in the composition of all the new explosives. The Japanese have, our contemporary states, limited and taxed the export of camphor, and its cost is therefore going up and may attain a high price; but if the Japanese push their advantage too far the *Spectator* thinks that science will avenge herself and provide a substitute.

THE SURGICAL TREATMENT OF EXOPHTHALMIC GOITRE.

DR. TUFFIER gives an interesting account of a case where surgical interference caused complete disappearance of all symptoms of the disease, which had resisted all other kinds of therapeutic treatment. The patient was a young woman aged twenty-seven, who had suffered with the malady for seven years and its beginning was marked by a cystic enlargement of the right lobe of the thyroid gland, which was soon accompanied by severe exophthalmos and the other usual symptoms. Iodine injections, tapping, and electrical treatment were all tried in vain, and the patient became so ill that she could not work, and, in addition, showed signs of distress from the pressure which the enlarged thyroid gland was producing on the trachea. It was then decided to perform partial thyroidectomy, and this was successfully accomplished, with the result that the general symptoms rapidly disappeared, the woman now being in good health and able to work. The exophthalmos also almost entirely disappeared and no other unpleasant symptoms have followed. Dr. Tuffier believes the success of the operation to lie in partial removal of the gland, which he thinks gives better results, both immediate and future, than complete extirpation of the organ.

LAY DIAGNOSIS AT WORCESTER WORKHOUSE.

THE Tewkesbury guardians have been instrumental in bringing to light what appear to be somewhat unsatisfactory methods of procedure at the Worcester workhouse. The guardians in question complained to the Local Government Board that a man suffering from skin disease—apparently scabies—was in effect refused medical advice at Worcester workhouse, and this in spite of the regulations as to casual

paupers, which provide that in the event of illness the master or superintendent of the casual ward should obtain the attendance of the medical officer. In this case the pauper, who was an inmate of the casual ward, requested to see the medical officer; he was, however, taken to the infirmary nurse, who, on her own responsibility, is reported to have administered medicine and even to have expressed the opinion that the man was in a fit condition to leave the institution. On quitting the workhouse the patient appears to have proceeded to Tewkesbury, where he was admitted into the workhouse and treated until well. It is difficult to regard this case as an isolated one, and we are tempted to generalise and say *ex uno disce omnes*. Whoever may be to blame in this instance it would certainly appear that the nurse in venturing to prescribe and to express what was practically a medical opinion acted *ultra vires*. A little knowledge is a dangerous thing, more especially when the possessor of it applies it to the differential diagnosis of skin eruptions. This, then, is another of the channels by which disease is spread amongst us, whether it be scabies or small-pox, and it may be that practices such as these have had something to do with the very substantial part which tramps have in recent years taken in the dissemination of variola.

ANTRAL EMPYEMA OF TUBERCULOUS ORIGIN.

A CASE of antral empyema, apparently of tuberculous origin, is recorded by J. Kekwick in the *British Journal of Dental Science* of May 15th. The patient, a woman aged thirty, complained of the usual symptoms indicative of antral empyema. The left upper second bicuspid was extracted and a free opening into the antrum made through the socket. For twelve months local treatment, combined with change of air and the administration of tonics, was carried out, but to no avail, the patient's condition remaining practically unchanged. The pus being of a curdy character and the history of the patient led to a suspicion of tubercle, &c., and on the discharge being examined microscopically, the tubercle bacillus was found in large quantities. Constitutional treatment for tubercle, combined with the insufflation into the antrum every day of powdered iodoform, lead to rapid improvement in the patient's condition, the discharge becoming less and the hectic condition which the patient had commenced to acquire being lost. The following reasons are given in support of the diagnosis: (1) the chronic course of the case, with no local causes such as loose sequestra; (2) the tuberculous character of the pus; (3) the amenability of the disease to iodoform; (4) the history of the patient (uncle died from phthisis; sisters suffering from phthisis; no signs of tubercle in the patient herself, but a queried history of tuberculous cervical glands—cicatrices); and (5) the bacilli in the pus which was washed directly out of the antrum through the nose.

THE PHARMACEUTICAL SOCIETY.

WHETHER or no it is because this society has come into greater prominence of late in connexion with the commendable activity it has exercised in repressing the indiscriminate sale of poisons and in watching over the conduct of practising pharmacists, there was an unusually large and influential company present at the annual dinner, held in the Whitehall Rooms of the Hôtel Métropole on May 21st, and it must be a source of considerable satisfaction to the members of this important and evidently prosperous society to find that they are vigorously supported by the leaders of all branches of science. The medical profession, to begin with, was very strongly represented by the President of the General Medical Council, Sir Richard Quain, Bart.; the President of the Royal College of Surgeons of England, Mr. Christopher Heath; the medical officer of the Local Government Board, Dr. Thorne Thorne, C.B.; Professor Burdon Sanderson, Sir Walter

Foster, M.P., and Sir Dyce Duckworth; while the learned societies were well represented by Professor Michael Foster, M.D., Secretary of the Royal Society; Professor A. Vernon Harcourt, F.R.S., President of the Chemical Society; Dr. Stevenson, President of the Society of Public Analysts; Dr. Russell, President of the Institute of Chemistry; Sir Frederick Abel, President of the Imperial Institute; and Professor T. E. Thorpe, President of the Society of Chemical Industry. In replying to the toasts (most of which were proposed from the chair by Mr. Carteighe, the President of the Pharmaceutical Society, and which included "The Houses of Parliament," responded to by the Right Hon. J. Bryce, M.P., President of the Board of Trade; "The Medical Profession," acknowledged by Sir Richard Quain and Mr. Christopher Heath; and "Science" by Professors Michael Foster and Vernon Harcourt) the speakers gracefully acknowledged their indebtedness to pharmacy and admitted also the importance to the community of the existence of a society such as the Pharmaceutical. Dr. Thorne Thorne proposed the toast of the society in a speech in which he confessed that, though he had to do with preventive rather than with curative medicine, he was none the less convinced of the value of drugs in therapeutics. An interesting and very successful gathering terminated with the toast of "Our Guests," to which Professor Burdon Sanderson, Sir Dyce Duckworth, and Dr. W. J. Russell replied in suitable and congratulatory terms.

INFECTIOUS HOSPITAL FOR CREWE.

A LOCAL government inquiry was held last week at Crewe by Dr. Sweeting on an application by the town council for power to borrow £8000 for the purposes of erecting a hospital for infectious diseases. The isolation of small-pox cases did not arise, since the town council have a small separate hospital for that purpose. Amongst the objections raised to the proposal was the fact that certain sums of money had been spent in maintaining the small-pox hospital during years when no cases of that disease had occurred and during one other year when the attacks admitted had been only two in number. It never seems to have occurred to the objector that the annual cost of an isolation hospital corresponds very much to a premium of insurance against infectious disease, and that to grumble because the premium is paid in years when there is no such disease is much the same thing as to grumble at having to pay a fire insurance premium during years when the building insured is not burned down. And as to a payment of £66 in one year when two small-pox cases were isolated, we can only ask what would have been spent in the borough if the cases had not been isolated and an epidemic had resulted? The other objections related mainly to the amount asked for being extravagant and the site not being the most suitable one. The evidence on this score was strongly refuted, and the question of its value may well be left to the central authority. In the meantime, we are pleased to note this evidence of sanitary progress on the part of the Crewe corporation.

TWO CASES OF CEREBRAL ABSCESS.

In the last number of the *Neurologisches Centralblatt* appears a short abstract of a paper by Dr. Nasse, which was originally published early in the year in the *Berliner Klinische Wochenschrift*. The first case was that of a man forty-three years of age who had received a perforating wound of the skull, and who eleven days after the accident experienced difficulty in speaking, and twitching of the mouth. He became apathetic, with slight fever and a pulse of 60. The diagnosis of abscess was arrived at, and the patient was trephined. The dura mater was perforated, and softened brain substance was extruded through the hole. An abscess was reached in front of the anterior

central convolution and evacuated. After the operation the general condition of the patient improved, but the facial paresis and the aphasia remained for a time, and right-sided general weakness was superadded. These symptoms, however, gradually subsided and a complete cure was effected. The second case was equally satisfactory. It was that of a boy aged six on whose head a piece of wood fell, and a nail in it was driven deeply into the head on the left side. There was vomiting on the day of the accident, and three days later interference with speech and twitchings on the right side. The general condition was good. Six days after the accident trephining was performed, and a piece of softening was found as large as a pigeon's egg in which were a number of bone splinters. After the operation the twitchings ceased, the aphasia disappeared, and the progress was uninterrupted.

THE DIFFUSION OF SMALL-POX.

THE Registrar-General tells us that there were in London in 1894 only 89 deaths registered from small-pox as compared with 206 in the preceding year, and that of these 89 24 were in vaccinated and 43 in unvaccinated persons, the state of vaccination of the remaining 22 deceased persons not having been ascertained. We further learn that of the vaccinated individuals not one was aged under five years, as against 26 in the unvaccinated class. In London in the fortnight ended last Saturday there were only some score of recorded cases of small-pox, and the number of patients remaining under treatment in hospital was at the close of each of the two weeks identical—namely, 27—not 1 death being registered; indeed, only 3 fatal cases have occurred since the beginning of March. The suburban districts have been free from the disease, and Bedford has had but slight continuance of the malady, cases having occurred in two or three instances only. Birmingham also retains the freedom from small-pox of which it has had such a large share in the past two years, and the southern midlands have been happily saved from any experience of invasion, except here and there a stray attack; but further north, Derby is passing through a somewhat severe outbreak of small-pox, which has in the two weeks numbered 30 or more cases, 22 occurring within the space of five days, and 30 patients being under treatment in the borough hospital on Saturday last. The original case seems to have been a tramp from near Ashbourne, who is stated to be responsible for the infection of 23 persons in the town of Derby, including three police constables who assisted in his removal to court on a charge of vagrancy and to the workhouse, wherein he died half an hour afterwards, he having been sent thither by the Bench out of charity in consequence of his condition. But all this time his illness had not been diagnosed as small-pox, nor indeed until death had supervened. Then two nurses at the workhouse caught the disease in laying out the body, a barmaid at a public-house where the man had called also developed the disease, and several inmates of two lodging-houses where he stayed have likewise developed small-pox, and other persons in different parts of the town, but mostly in the vicinity of the lodging-houses, have been notified as suffering from small-pox. The hospital at Little Chester contains fifty beds, and it is intended to erect temporary accommodation if this should unhappily prove necessary. In the meantime the health officials are doing all in their power to minimise the chances of the spread of the epidemic. Not far away—at Ripley—there have been two cases of the disease discovered in two lodging-houses, the one in the person of a man who has been sent to the Derby Hospital and the other in a child, the lodging-house having been ordered to be closed. One or two attacks have occurred in and around Liverpool in the last fortnight, and other towns in Lancashire, as Bolton and

Wigan, have had to deal with odd cases, as also Manchester, the infected person being removed to the Clayton Hospital. In Dublin matters have certainly improved of late, and in the two weeks ended May 18th there were but 15 and 12 admissions respectively to hospital, the 61 patients under treatment a month previously having decreased to 44, though there have to be added to the latter number 35 convalescents in hospital at Kilmalnam. Only one death took place in the two weeks, of a person aged over twenty years and vaccinated. These data serve to show that the epidemic is on the wane in the city.

THE BORDEAUX CONGRESS OF GYNÆCOLOGY, OBSTETRICS, AND PÆDIATRICS.

THE Congress of Gynæcology, Obstetrics, and Pædiatrics, which was to have been held at Bordeaux on Aug. 12th, is to take place four days earlier—namely, on Aug. 8th. Medical men desirous of taking part in the congress are desired to signify their intention of so doing as soon as possible to the secretary, Dr. Lefour, Rue Duffour Dubergier, 11, Bordeaux.

THE INCORPORATED MEDICAL PRACTITIONERS' ASSOCIATION.

THIS young association has acquired strength in the course of the past year under the vigorous guidance of Dr. Eady, who has now retired in favour of a provincial president—Mr. George Jackson, F.R.C.S. Eng., of Plymouth. Its membership has increased, especially in the provinces. One of the members justified the existence of the association as a distinct society on the ground that the British Medical Association was giving too little attention to the interests of men in general practice. This view is scarcely tenable, but it is worthy of note by the larger association. The questions which chiefly occupied the association were those of the medical aid associations and the Midwives Registration Bill. A necessity for some legislation with regard to midwives was admitted, but the feeling was in favour of highly trained nurses rather than midwives proper. A deputation was appointed to wait on the General Medical Council on the subject of medical aid associations and kindred devices for sweating medical men. The executive committee of the Council have considered this request, but have declined to recommend the Council to receive the deputation, seeing that the Council has already considered and reported on the subject of such associations. Among other features of the association are an insurance department and an arbitration board. What is wanted in the profession is a strong *esprit de corps* which will lead to united action not only in large centres but in smaller ones. A cordial coöperation between such associations and the medical authorities would help much to preserve the prestige of the profession. An account of the annual meeting and dinner of the association will be found opposite.

At the Levée held at St. James's Palace on Monday last the following gentlemen were presented to H.R.H. the Prince of Wales on behalf of Her Majesty the Queen: Dr. Allchin, by the Duke of Westminster, K.G.; Dr. T. Lauder Brunton, by Sir Trevor Lawrence, Bart.; Dr. Radcliffe Crocker, by Sir John Russell Reynolds, Bart. (Physician to the Household); Sir John Eric Erichsen, Bart., and Sir John Russell Reynolds, Bart., by the Earl of Rosebery, K.G. (First Lord of the Treasury); and Mr. Christopher Heath, President of the Royal College of Surgeons, by Lord Ribblesdale.

We understand that there is a somewhat severe outbreak of typhoid fever in Plumstead and Woolwich, attributable, it is alleged, to milk contamination.

At a meeting of the governors of the Middlesex Hospital on May 28th Mr. Leopold Hudson, F.R.C.S. Eng., aural surgeon to the hospital, and assistant surgeon to the Hospital for Sick Children, Great Ormond-street, was elected assistant surgeon to the Middlesex Hospital, in succession to Mr. Andrew Clark, who has been recently appointed surgeon.

THE INCORPORATED MEDICAL PRACTITIONERS' ASSOCIATION.

THE annual meeting of this Association was held at the Holborn Restaurant on Thursday, May 23rd. Among those present were Dr. G. J. Eady (President), Mr. George Jackson, F.R.C.S. (President-elect), Dr. J. W. J. Oswald, Dr. F. H. Alderson and Mr. George Brown (Vice-Presidents), Mr. R. J. W. Oswald and Mr. Frank Greaves (hon. sec.), Dr. Bedford Fenwick (hon. treasurer), Mr. J. B. Cook, Dr. J. Pollock Simpson, Dr. Mark Sharman, Mr. A. G. Beale, Mr. H. Rainsford, Mr. J. L. Callaghan, Dr. Rivers Willson, Dr. J. W. O'Brien, Mr. A. Primrose Wells, Dr. Fletcher Beach, Dr. R. M. Benton, Dr. R. Paramore, Dr. Andrew Murray, Mr. H. Banks, Mr. A. Kisch, and Mr. M. Cursham Corner.

The annual report stated that the number of members had been nearly quadrupled during the past twelve months, and whereas formerly the majority resided in the metropolis there was now a very large proportion who practised in the provinces, in Scotland and Ireland. The debt-collecting department had obtained a fair measure of success. The sale and transfer of practices department had been thoroughly organised, and was now available for the assistance of members. The legal assistance department secured from the solicitor to the Association first-class legal advice and assistance at much reduced charges. There had been no necessity for a formal arbitration during the past year; but in various cases the Council had advised upon differences which had arisen between members and other practitioners, or other persons outside the profession, and in all but one of these cases the advice had been adopted and further trouble prevented. In several instances members had insured their lives or property through the agency of the Association, and had thereby saved themselves a considerable sum, while the funds of the Association had also benefited to a similar extent. The Council considered that the dangers to which the poor were at present exposed at the hands of ignorant and incompetent midwives were too great to be ignored, and it therefore recommended the members to authorise the Council to carry out a scheme for the improvement of the education and control of a new class of workers, in the shape of obstetric nurses who shall not be certificated until they are properly trained and efficient, and who will be required to work directly under the supervision of medical men.

Among the resolutions discussed at the meeting and unanimously carried was one proposed by Dr. Bedford Fenwick, and seconded by Dr. Alderson, approving of the scheme suggested by the Council for the better education and control of obstetric nurses, and authorising the Council to carry the same into effect.

On the motion of Mr. George Brown, seconded by Mr. George Jackson, the following resolution was passed *nem. con.*: "That this meeting considers that the Bill at present before the House of Lords would, if passed into law, be fraught with the greatest danger to the public, and especially of the poor women of the labouring classes, who would thus be misled into believing that women qualified under this Act were really skilled practitioners of midwifery. This meeting considers that such legislation would largely tend to undo the good effects secured by the Medical Act, and would be harmful to the whole community by placing the practice of midwifery upon a lower level of skill and efficiency than that required from other branches of the medical art."

On the motion of Mr. A. G. Beale a resolution strongly approving of the action of the Council with regard to medical aid associations, and appointing a deputation to wait upon the General Medical Council and present to that body petitions signed by registered medical practitioners against the action of medical aid associations, was also carried.

Dr. Eady, Mr. Brown, Mr. Beale, Dr. Oswald, Mr. Greaves, and Dr. S. Jarman were elected to form the deputation.

A resolution authorising the Council to promote such a scheme of home hospitals and out-patients' dispensaries as may seem to be most suitable to the needs of general practitioners and the public was unanimously adopted.

Dr. Eady then delivered his valedictory address, in which he referred to his successful year of office and the help he had received from the Council and officers of the Association. He briefly passed in review the work of the year and called attention to the insurance department, which helped both the insured and the Association. He also referred to the success of the arbitration board. Referring to the friction between medical officers of health and practitioners, he thought a little good sense and kindly forbearance would effectually smooth over any difficulty that might otherwise arise. In conclusion, he paid a tribute to the memory of Dr. Henty, who had gone to his rest full of years and honour, and who had left behind a name that would always linger in the hearts of those who knew him.

Dr. Eady then conducted Mr. Jackson to the presidential chair, and the meeting came to a close with the usual compliments to the chairman.

THE DINNER.

The members present afterwards adjourned to the Queen's Salon for dinner, where Dr. Eady again took the chair. He was supported by Sir Walter Foster and Dr. J. G. Glover, and many friends and members of the Association, besides those present at the previous gathering, rallied round the retiring President.

The loyal toast of "The Queen" having been duly honoured,

Dr. Eady proposed the toast of the evening, "The Incorporated Medical Practitioners' Association." After referring to the satisfactory position of the Association, he passed to the question of the Midwives Bill. He was sorry to say a few members of the profession had separated themselves from the great majority, and because the latter did not think with them it was assumed that they did not want legislation on this important point. That was an error. They were fully alive to the evils of the present day and were anxious for legislation to remedy the existing state of things. They objected to the Midwives Registration Bill because it would in no way tend to mitigate those evils, but, on the contrary, would increase them tenfold and foist on the general public a large number of practitioners belonging to an uneducated class who would know just enough to be dangerous, and if licensed would with difficulty be constrained or controlled. There were no penal clauses in the Bill, and no penalty was provided in cases of a complicated character. Still-born children would become more common and other offences against the law would be rife. The Association had not confined itself to finding fault with the Bill, but had adopted an alternative scheme. The present Bill started with the assumption that a midwife was a necessity. He maintained that a midwife was not a necessity. What had been done for sick nursing must be done for obstetric nursing. This was not to be done by three months' training. A better class of women must be taken and given a longer and better training. The scheme referred to did away with a midwife and substituted for her the obstetric nurse. Two years' general training as a sick nurse and one year's special training were proposed.

The President-elect, Mr. George Jackson, spoke of the harm that the medical aid associations had done in Plymouth.

Dr. Bedford Fenwick proposed "The Visitors," coupling with the toast the names of Sir Walter Foster and Dr. James Grey Glover.

Sir Walter Foster, M.P., Parliamentary Secretary to the Local Government Board, in responding, said he had made a special effort to be present at this dinner in order that he might show the interest which he took in the work of the Incorporated Medical Practitioners' Association, and to apologise for his absence on previous occasions. No man had a greater interest than he had in the thorough training of women to look after their sisters in the peril of labour, and he was sure that all would desire to place them in a better position; but he looked upon the present Bill as a severe blow not only to the public, but to the profession. The Midwives Registration Bill, he thought, was a contravention of the Medical Acts of 1886. He had laid it down in a Minute, which he hoped the Local Government Board would be guided by, that no woman was to be recognised by the Local Government Board

as capable of attending midwifery cases unless she was fully qualified in medicine, surgery, and midwifery. If she had not those three qualifications she must attend cases only under the direct superintendence of a medical officer. He (Sir Walter Foster) stated that he had given notice to the General Medical Council that at their meeting in the ensuing week he would move the following resolution: "That this Council, while desiring to improve the education, training, and control of women who act as midwifery nurses, is unable to give any support to the Midwives Registration Bill, inasmuch as that Bill would give women a legal status to undertake the sole charge of cases of midwifery, for which no persons are qualified unless qualified in medicine, surgery, and midwifery." Speaking of the competition among medical men, he said all attempts to raise salaries of medical officers were rendered futile. Cases were sent up to him where he considered the fees inadequate, but if he told the local bodies so they replied that they could have half a dozen medical men at the same price. As long as this ineane competition went on no Minister, however strong his desire might be to benefit them, could do any good.

Dr. Glover congratulated the Incorporated Medical Practitioners' Association upon the satisfactory state of its affairs. He wished to touch for a few moments on the question of the Midwives Bill, but he could not help feeling that there were other matters of importance besides this Bill, and he did not wish them to lose sight of other things which were eating into the dignity and character of the profession. There were members of the profession pursuing methods of practice on a huge scale which would very seriously alter its whole character. With regard to the Midwives Bill he recognised with pleasure the amount of unanimity among them. He was deeply sensible of the evils caused by untrained midwives, and some remedy must be found. He recognised the respect that had been paid to the General Medical Council, and he believed that that body would not wantonly disregard the interests of the profession. It was suggested that the women should have three years' training like the highly trained nurse. But such highly trained nurses were the luxury of the rich. The only way to supply them to the classes who now employ midwives would be to make midwifery free, like education, and throw it on the rates. This would be a serious course, and one of very questionable advantage to the profession. If the provision of a humble class of midwives acting in strict subordination to medical men is a blow to the profession, the provision of a class of highly trained nurses would be "a staggering blow."

Other toasts followed, and the meeting was brought to a close.

THE ROYAL MILITARY TOURNAMENT.

THE Royal Military Tournament now being held at the Agricultural Hall, Islington, promises to prove in every way as successful as its predecessors and in many respects to surpass them. From a spectacular point of view it is a decided success, and we sincerely hope that when the Tournament closes on June 6th we may say as much from a financial point of view. To Colonel Onslow and to Colonel Tully and his committee the highest praise is due, not only on account of the efforts they have put forth to please the public, but also for the way in which they have endeavoured to minister to the health and comfort of the troops.

The main object of the Royal Military Tournament is to provide money for military charities; but apart from this the amount of good that must be done to the soldier throughout the British army, both moral and physical, is almost incalculable. Only the men who have proved their ability at local tournaments are allowed to compete at the Royal Military Tournament, and thus a spirit of emulation is fostered among the troops for the honour; and this increased interest in feats of strength, skill, and precision must necessarily improve the moral tone, for intemperance of living and high physical skill are incompatible. No colonial troops have entered for competition this year, but almost all branches of the services are represented, and a small contingent of the Egyptian army, or fellahien soldiery, under the command of Sergeant-Major De Vere, a past instructor in the gymnasium at Aldershot, who go through some gymnastic exercises, show what excellent soldiers they make when properly trained.

It is invidious to single out any one item from the programme, but the grand historical military pageant and the display by non-commissioned officers deserve at least a passing word of notice. In the former the 3rd (King's Own) Hussars and the Buffs march past dressed in the various costumes worn by the respective regiments from Stuart times to the present day. Both foot and horse soldiers are represented, and the pageant, in regard to which no efforts have been spared to make it historically accurate, down to the minutest details of the horses' bridles, reflects great credit upon its organisers and makes it one of which they may be justly proud. The other display to which we have referred is under the command of Colonel Fox, and illustrates the system of physical exercise as taught to recruits and soldiers in the army. Major Greatrex is also responsible for the training. About sixty of the 140 non-commissioned officers now under training at the head-quarter gymnasium at Aldershot, representing different branches of the service, go through a drill which develops in a scientific manner, not only the muscular strength, but also the intellectual faculties. It would be difficult to explain the *modus operandi* of the exercises on paper, and it must suffice to say that while equal attention is paid to the upper and lower limbs all the muscles of the trunk are brought into play. After six months' training (working five hours a day) the chest measurement on an average increases by three inches, and a most desirable sense of interdependence is developed among the men. To a certain extent they each act independently; the system teaches them to support each other under difficulties, and, besides generally "sharpening" them up, we are assured that the moral effect is great, and that the men feel no tendency to indulge in those intemperate habits to which the ordinary soldier is too often unfortunately addicted. The object of the training is that the men shall qualify at the end of six months for a gymnastic certificate in order that they may go back to their regiments as instructors. Every regiment is obliged by regulations to have at least three of these instructors on its strength. This regulation will have the effect in a very short time of showing a great improvement in the physique of our army. Colonel Fox endeavours to maintain in his men that *mens sana in corpore sano* which shall fit them for the exigencies of modern warfare, and the rapidity of movement and precision of action displayed by the men under his command seem to show that that end has been attained.

From time to time during the fortnight that the Tournament is in progress as many as 1500 troops, representing every branch of the service, occupy the building, and 300 horses are in requisition. This year, as last, the men are quartered in cubicles instead of in tents, and as far as is possible everything is done to ensure their comfort. The mess-rooms are well provided, and the food and cooking excellent. One thing that seems to have escaped attention, however, might easily be remedied. The cubicles are erected in the galleries immediately below skylights, and the rays of the sun pouring down on the men must only tend to discomfort, especially after a hard contest in the arena. Draw-blinds, or even a strip of canvas, would obviate this, and the cost would be infinitesimal. The sanitary arrangements are almost as perfect as can be desired, the latrine accommodation is sufficient, and the water-supply is quite satisfactory. There is a little more ventilation than last year, but in this direction there is still much room for improvement. What is really wanted is a steam punkah, or something of that kind, to force the air through the building, and until this is supplied the ventilation cannot be considered satisfactory. Another point that calls for attention is the non-efficient lighting of dark corners. In the stables peat moss is used in the place of the ordinary litter, and so well are they kept that the absence of effluvia is remarkable. The foul litter is cleared away twice a day, and the scavenging, which is very systematic, takes place between 5 and 6 A.M., when the horses are out for exercise, and the last thing at night. This year some of the horses have been stabled outside the building upon some adjacent ground, and this necessarily is an advantage from a hygienic aspect. In order to lessen the risk of fire the forage is stored outside the building.

Surgeon-Major Tyrrell, A.M.S., who is assisted by Surgeon-Lieutenant Cameron, A.M.S., is the principal medical officer in charge of the troops, and the remarkably good health of the latter speaks well for the ability of these officers. Surgeon-Major Tyrrell has made every effort to induce the authorities

to adapt the building to hygienic requirements, and in a very great measure his efforts have been crowned with success. There has been only one hospital case, diagnosed as influenza, and this has been sent to the divisional hospital. No serious accidents have occurred. The temporary hospital is advantageously situated outside the building, where almost perfect quiet can be maintained, and is fitted with two beds and all the necessary medicines and appliances required in a hospital of this kind. An orderly is in constant attendance.

The ambulance department is under the command of Surgeon-Major Lawless, Army Medical Reserve, and ample arrangements are made to treat any accident that may happen to the audience. A trained orderly is always stationed close to the spectators with a bag containing splints, dressings, &c., and there are two dressing stations in the Arcade, which have been fitted up with all necessary material by Messrs. Evans and Wormull, 31, Stamford-street, for male and female cases. Two trained orderlies are in attendance at the male station, and Miss C. J. Woodward and Miss A. Woodward are the Sisters who minister to the female cases.

NATIONAL HEALTH SOCIETY.

A MEETING of this society took place at Grosvenor House on May 11th. Dr. Edward Seaton, after commenting on the excellent course of instruction given by the lecturers appointed by the society and the success achieved by Surrey students, proceeded to offer a few remarks under the following heads—viz.: (1) the advantages of popular teaching in matters relating to public health; (2) rural sanitation as part of popular teaching; and (3) village nurses.

1. *The advantages of popular teaching in matters relating to public health.*—This he illustrated by past experience in relation to improved dwellings for the working-classes. In 1875 he had, at the suggestion of a well-known citizen of Nottingham, Mr. Richard Esfield, inaugurated lectures on health, especially in relation to the influence of dwellings and the necessity for sufficient light and air about them. At that time the town council of Nottingham was attempting to deal with unhealthy areas (rookeries) by street improvements. That was a highly important work, but it was still more important that the dwellings of the future should be built with sufficient air space about them. The Local Government Board had issued an admirable series of model by-laws to ensure this, but it needed the force of local public opinion to secure their adoption and observance. Land-owners and builders were a powerful class, and they were generally more than sufficiently represented on town councils and local governing bodies. Their views did not always coincide with those of the guardians of the public health in the essential matter of light and air about dwellings. For that reason public opinion needed to be created or aroused. He (Dr. Seaton) found that popular lectures were most useful for this purpose. He could not but think that in London they were much wanted, as he had in the course of inquiries made about four years ago, under the directions of the Home Office, become acquainted with cases where lofty buildings, arranged on the "flat" system, had been allowed to be erected—in the East-end—under conditions that made it impossible that the lower dwelling-rooms could ever be penetrated by the sun's rays. There were other illustrations he could give of the advantages of popular teaching as to public preventive measures; as an instance he mentioned the notification of infectious diseases, a system which had been adopted throughout the whole county of Surrey in a voluntary manner.

2. *Rural sanitation as part of popular teaching.*—He then spoke of the views of Miss Florence Nightingale as to the need of giving instruction to cottagers and members of parish councils respecting the best methods of safely disposing of refuse matters—liquid and solid—so as to prevent country dwellings and their immediate surroundings from becoming unhealthy. Dr. Poore had partly dealt with this subject in his most interesting and valuable book on Rural Hygiene. He (Dr. Seaton) believed the subject to be one of vital importance to dwellers in the country. It was constantly before him in connexion with river pollution, which had from the first engaged the attention of the Surrey County Council, whose responsible adviser and official he was. The

remedy always suggested for a state of things almost invariably found in the country was the establishment of drainage or sewerage schemes. But although everyone was agreed at the present day as to the necessity for such provision in towns, it by no means followed that sewerage systems were equally advantageous in sparsely populated rural districts. At any rate, the circumstances of the closely built town and the village or parish consisting of clusters of houses situated widely apart were so obviously different that it should be seriously considered whether they did not call for essentially different treatment. It was for that reason that he would urge on the society the desirability of extending the sphere of their teaching so as to include all matters pertaining to rural sanitation.

3. *Village nurses.*—He came now to the brief consideration of a rather delicate topic—delicate because of the many and complicated considerations involved. He understood from conversation with Mr. Macan that among the supporters of technical education were some who thought it practicable to make the nursing of the sick and of women in childbirth part of the system of technical education carried on under the auspices of the society. As he had no connexion with medical practice he might speak more freely than others on this matter. He felt it right to remind them that nursing was an art not to be acquired without a long, special, and systematic training. The difference between the art of the nurse and the profession of the medical man was, of course, essential, and needed not to be insisted on for a moment. But there was this in common—they both required a long course of special training. There were at the present day some lady members of the medical profession, and he hoped there would be many more. They would be the first to understand the difference between the person who had merely succeeded in acquiring a considerable amount of technical knowledge or skill and the trained nurse who, by discipline or associations, had in addition learnt to understand the ethics (if he might so use the word) of her business. Cleanliness and tidiness, personified as they were by the nurse, were naturally objects of aspiration among the members of the society; but, if he rightly understood the views of some, the considerations he had named were, he thought, not out of place on the present occasion, his remarks being intended as words of caution on a subject of great practical importance.

ROYAL MEDICAL BENEVOLENT COLLEGE.

At the annual general meeting, held on May 30th, at the offices of the College in Soho-square, the following candidates for pensionerships and foundation scholarships were reported by the scrutineers—Dr. M. Baines, Dr. Frederick Taylor, and Colonel Gordon Watson—to have obtained the largest number of votes, and were declared to have been duly elected:—

Pensionerships.

1. Mathias, Dinah G. ...	6750	3. Rust, Thomas P. ...	4956
2. Moffat, Elizabeth G. ...	5463	4. Guy, Eleanor, M. C. ...	3330

Foundation Scholarships.

1. Arnold, Alwyne C. ...	7736	5. O'Meara, Hubert ...	4456
2. Snow, Edward L. R. ...	7650	6. Mac Sheehy, James G. J. ...	4340
3. Cummins, Arthur G. ...	5935	7. Kinder, Kenneth ...	3935
4. Twining, Daniel O. ...	4685	8. Jenkins, Reginald L. ...	3609

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Chelsea Urban Sanitary District.—In his annual report for 1894 Dr. Louis Parkes, in dealing with the water-supply of Chelsea, refers to the unsatisfactory character of the Thames at Hampton Court as a source of drinking water for London. He points out that in every month of the year the water of the Thames was described as turbid and yellow, while in January it was reported to be "very turbid and pale-brown," and in November "extremely bad." It cannot be doubted, Dr. Parkes states, that at times the raw material on which the water companies are required to operate is in a

highly polluted condition, and he insists upon the paramount importance of continual care and watchfulness in conducting the filtration. All will agree with him on this point—those who have the immediate control of the filter-beds are in a position of enormous responsibility, as also are those who examine the water from time to time bacteriologically and chemically.

Stoke Newington Urban Sanitary District.—That the value of compulsory notification is not limited to the control of the cases notified is patent to all, but it is nevertheless well from time to time to note some of the other advantages which the knowledge obtained by notification affords. Dr. H. R. Kenwood, in reporting on his district for 1894, points out that the notifications received during the last forty weeks of the year were instrumental in bringing about a sanitary inspection of 117 houses, in which 46 "grave" and 56 "slight" sanitary defects were remedied. He also draws attention to the fact that notification leads to the discovery of sanitary defects at a time when the occupiers of infected houses are easily influenced to procure improvements. Dr. Kenwood states that in 1894 he examined the exudation from a severe sore-throat and found no diphtheritic bacilli, whereas forty-eight hours afterwards he detected them in large quantities. He mentions this case as an illustration of the danger of arriving at a conclusion from one examination only. As regards water-supply, Dr. Kenwood reports that the greater part of Stoke Newington is supplied with water on the intermittent system, and the cisterns, he states, are often in very undesirable positions.

Surbiton Urban Sanitary District.—Among the cases of enteric fever incidence in Surbiton during 1894 was one which the medical attendant considered was probably contracted from eating oysters, the patient's companion, who apparently consumed oysters at the same time, being subsequently attacked by the disease. It would have added to the interest attaching to these two cases if the dates of the consumption of the oysters and the attacks had been given. It is the accumulation of cases such as these which may eventually form a valuable body of evidence. Dr. Owen Coleman in his report also draws attention to the number of typhoid fever cases developing in this country which in all probability were contracted abroad. As he points out the gradual feeling of malaise &c. with which attacks of enteric fever usually begin leads the traveller to turn his steps homeward and to swell the typhoid fever attack and death-rate in his own country. Dr. Coleman has, he states, met with cases which contracted the disease in Vienna and even in Chicago.

The Strand Urban Sanitary District.—Commenting upon the subject of oysters and enteric fever in his annual report for 1894, Dr. Francis Allan observes that out of nineteen cases of the disease notified in his district no less than seven were employed in hotels and restaurants, and one of these persons was also an oyster merchant. Amongst the more important drainage works carried out in the Strand during 1894 we are glad to note the re-drainage of the Gaiety and Lyceum Theatres and the Royal Italian Opera House. The Strand sanitary authority have now a shelter under Section 60 of the Public Health (London) Act available, but Dr. Allan adds that "it is a general experience that persons do not care to make use of such accommodation."

Bournemouth Urban Sanitary District.—Mr. Philip Nunn reports that in May, 1894, a sharp outbreak of variola was occasioned by a man who had apparently contracted the disease near London. The notification of the case only reached Mr. Nunn when the patient was in the pustular stage of the disease. This case gave rise to twelve others, one being, we regret to see, that of a laundry maid at the fever hospital. Mr. Nunn states that during a period of eighteen years he has had to contend with eight outbreaks of small-pox, and that in every case the disease has in the first instance been imported from a distance. The practice of granting sanitary certificates to householders has, he thinks, increased the confidence of visitors to Bournemouth. During 1894 135 applications for such certificates were made to the sanitary authority, and the sum of £140 5s. was received in fees.

Bristol Port Sanitary District.—During the year 1894 a permanent port sanitary authority for this district was constituted by the Local Government Board, and Dr. D. S. Davies gives in his report a capital sketch map showing the limits of the port sanitary authority's jurisdiction. The arrangements made during 1894 for securing the medical inspection of vessels arriving from suspected ports were the same as those in the preceding year, and day and

night inspection was carried out by the port medical officers from Aug. 8th to Oct. 28th. Although no actual case of cholera was introduced into the port of Bristol during 1894 several vessels arrived from infected ports in which there had been suspicious cases of diarrhoea. The report of the chief port sanitary inspector, Mr. Dimond, which is appended to Dr. Davies' report, shows that very good work is being done in this district in the matter of the sanitary supervision of vessels.

Uxbridge Urban Sanitary District.—Mr. William Rayner, in his current annual report, draws attention to the fact that in some instances he found samples of water in his district contaminated by sewage and gas. This contamination he regards as being due to defective service pipes, some of which have been laid at least forty years. By the in-suction of specifically polluted filth into defective service pipes Mr. Rayner accounts for some cases of enteric fever which occurred in his district.

Ormskirk Rural Sanitary District.—Mr. Herbert Peck, in urging his sanitary authority to provide proper isolation accommodation, reminds them that without such a hospital and proper means of disinfection full benefit from the compulsory notification of infectious disease cannot be obtained. As an illustration of the difficulties with which he has to contend, Mr. Peck cites instances where infectious disease might probably have been controlled had isolation provision been procurable. In one case a trained nurse contracted enteric fever from one of her patients, owing, it appears, to the impossibility of taking proper precautions. It certainly seems very unfair to place a medical officer of health in a position where he is expected to control the spread of infectious disease without a hospital and without a disinfecting apparatus. The information conveyed by the Infectious Disease (Notification) Act will not enable a medical officer of health to do much for his sanitary authority unless the Act is supplemented by efficient machinery.

Mile-End Urban Sanitary District.—Mr. Thomas Taylor furnishes in his current report a *résumé* of Dr. Hamer's report to the London County Council on the sanitary condition of the district. The inquiry, Mr. Taylor states, was instituted owing to the report of the Jewish Board of Guardians for 1893, which raised questions as to the adequacy of the sanitary staff. Dr. Hamer made a very thorough inspection of the district, and his report revealed the fact that much good work had been and is being done. The whole tenour of Dr. Hamer's report, Mr. Taylor states, conclusively shows that the report of the Jewish Board was "misleading and highly coloured."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6432 births and 3529 deaths were registered during the week ending May 25th. The annual rate of mortality in these towns, which had been 17.7 and 17.6 per 1000 in the two preceding weeks, further declined last week to 17.4. In London the rate was 16.3 per 1000, while it averaged 18.2 in the thirty-two provincial towns. The lowest rates in these towns were 9.5 in Croydon, 10.1 in Portsmouth, 11.8 in Leicester, 12.0 in Gateshead, and 13.1 in Huddersfield; the highest rates were 21.8 in Salford, 23.2 in Bolton, 25.1 in Burnley, 26.0 in Manchester, and 27.3 in Liverpool. The 3529 deaths included 354 which were referred to the principal zymotic diseases, against 351 and 304 in the two preceding weeks; of these, 95 resulted from whooping-cough, 84 from measles, 65 from diphtheria, 55 from diarrhoea, 29 from "fever" (principally enteric), 26 from scarlet fever, and not one from small-pox. No fatal case of any of these diseases occurred last week in Gateshead; in the other towns they caused the lowest death-rates in Leicester, Oldham, Swansea, and Birkenhead, and the highest rates in Salford, Liverpool, Bolton, Plymouth, and West Ham. The greatest mortality from measles occurred in Plymouth, Cardiff, Newcastle-upon-Tyne, West Ham, and Bolton; and from whooping-cough in Norwich, Sunderland, Bolton, Salford, and Plymouth. The mortality from scarlet fever and from "fever" showed no marked excess last week in any of the large towns. The 65 deaths from diphtheria included 37 in London, 5 in West Ham, 4 in Wolverhampton, 3 in Liverpool, and 3 in Birmingham. No fatal case of small-pox was registered either in London or in any of the thirty-two large

provincial towns. There were 29 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, May 25, against 34, 33, and 27 at the end of the three preceding weeks; 7 new cases were admitted during the week, against 8, 6, and 4 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1503, against 1413, 1438, and 1446 on the three preceding Saturdays; 214 new cases were admitted during the week, against 107, 179, and 185 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 247 and 240 in the two preceding weeks, rose to 245 last week, but were 67 below the corrected average. The causes of 60, or 1.7 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Nottingham, Bradford, Newcastle-upon-Tyne, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Swansea, Birmingham, and Leicester.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18.7 and 21.1 per 1000 in the two preceding weeks, declined again to 20.2 during the week ending May 25th, but exceeded by 2.8 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14.5 in Paisley and 15.2 in Edinburgh to 23.1 in Glasgow and 23.3 in Aberdeen. The 584 deaths in these towns included 19 which were referred to diarrhoea, 18 to measles, 17 to whooping-cough, 4 to scarlet fever, 3 to diphtheria, 3 to "fever," and not one to small-pox. In all, 64 deaths resulted from these principal zymotic diseases, against 59 and 66 in the two preceding weeks. These 64 deaths were equal to an annual rate of 2.2 per 1000, which was 0.5 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 30 and 24 in the two preceding weeks, further declined to 18 last week, of which 4 occurred in Aberdeen, and 3 each in Glasgow, Edinburgh, and Leith. The deaths referred to whooping-cough, which had been 17 and 14 in the two preceding weeks, rose again to 17 last week, and included 12 in Glasgow. The fatal cases of scarlet fever, which had declined from 7 to 1 in the three preceding weeks, rose again to 4 last week, of which 2 occurred in Glasgow and 2 in Edinburgh. The 3 deaths from diphtheria were within one of the number in the preceding week, and were all recorded in Glasgow. The fatal cases of "fever," which had been 3 and 5 in the two preceding weeks, declined again to 3 last week. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 98 and 109 in the two preceding weeks, declined to 103 last week, but exceeded by 14 the number in the corresponding week of last year. The causes of 43, or more than 7 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27.4 and 27.7 per 1000 in the two preceding weeks, further rose to 28.5 during the week ending May 25th. During the past eight weeks of the current quarter the death-rate in the city has averaged 30.0 per 1000, the rate during the same period being 17.6 in London and 18.8 in Edinburgh. The 191 deaths registered in Dublin during the week under notice showed an increase of 5 upon the number in the preceding week, and included 7 which were referred to the principal zymotic diseases, against 7 and 5 in the two preceding weeks; of these, 3 were referred to whooping-cough, 2 to small-pox, 1 to "fever," 1 to diarrhoea, and not one either to measles, scarlet fever, or diphtheria. These 7 deaths were equal to an annual rate of 1.0 per 1000, the zymotic death-rate during the same period being 1.7 in London and 1.5 in Edinburgh. The fatal cases of whooping-cough, which had declined from 4 to 1 in the three preceding weeks, rose again to 3 last week. Two deaths were referred to small-pox, making 12 deaths from this disease registered within the city during the present quarter. The 191 deaths in Dublin last week included 31 of infants under one year of age and 54 of persons aged upwards of sixty years; the

deaths both of infants and of elderly persons exceeded those recorded in any recent week. Four inquest cases and 2 deaths from violence were registered; and 77, or more than a third, of the deaths occurred in public institutions. The causes of 14, or more than 7 per cent., of the deaths in the city last week were not certified.

HEALTH OF THE SMALLER ENGLISH TOWNS IN 1894.

One of the most interesting features of the annual summary for 1894 recently issued by the Registrar-General is the statistical information it contains bearing upon the health and sanitary condition of sixty-seven towns other than the thirty-three great towns specially dealt with in the weekly and quarterly returns. The thirty-three great towns, including London, had an estimated population of nearly ten millions and a half in the middle of 1894, and the estimated population of the sixty-seven other large towns was at the same date rather more than three millions and a half. Thus the estimated population of the 100 largest English and Welsh towns in the middle of last year exceeded fourteen of the thirty millions estimated to be living in England and Wales. The smallest of these sixty-seven towns are Dover and Scarborough, with populations respectively estimated at 34,349 and 34,913. The three largest towns are Middlesbrough, with 83,278; South Shields, with 87,007; and Ystradgynodwg, with 102,683 inhabitants respectively. The mean birth-rate in the sixty-seven towns in 1894 was 30.5 per 1000, 0.9 above the mean rate in England and Wales and almost identical with the rate in the thirty-three larger towns, which was 30.7. The birth-rate in the several towns ranged from 18.4 and 18.9 in Bournemouth and Hastings, to 37.8 in Wigan, 39.6 in Warrington, and 39.7 in Longton. The mean recorded death-rate in the sixty-seven towns did not exceed 16.0 per 1000, and was 2.1 below the mean rate in the thirty-three larger towns. It is also especially worthy of remark that the mean rate in these sixty-seven towns, with populations ranging between 34,000 and 87,000, was in 1894 0.6 per 1000 below the mean rate in the whole of England and Wales. The recorded death-rates in the individual towns showed, however, a very wide range; the lowest rates were 9.5 in Hornsey (which is rather a London suburb than a town in the ordinary sense of the word), 10.0 in Bournemouth, and 10.3 in Eastbourne; while the rates ranged upwards to 20.7 in Merthyr Tydfil, 21.8 in Exeter, 22.0 in Longton, and 22.1 in Dudley, these being the only towns among the sixty-seven in which the death-rate last year exceeded 20 per 1000. It may confidently be asserted that in no other country in the world could such satisfactory urban mortality statistics be published. The mean death-rate from the principal zymotic diseases in the sixty-seven towns was 1.68 per 1000, against 2.44 in the thirty-three larger towns, and 1.76 in England and Wales. The fatality of small-pox, measles, and diphtheria in the sixty-seven was less than half that recorded in the thirty-three towns, and the death-rate from scarlet fever, whooping-cough, and diarrhoea also compared very favourably with that in the larger towns. Fever, principally enteric, was the only disease of this class that was more fatal in the small than in the larger towns; the highest fever-rates were 0.56 per 1000 in Barnsley, 0.59 in Bury, and 0.63 in Bootle. Scarlet fever showed fatal prevalence in Bootle and Warrington; diphtheria in Rochdale; and measles in Exeter and Dudley. Judged by the test of infant mortality the returns from the smaller towns were relatively more unfavourable, the deaths of infants under one year to 1000 registered births averaging 143, against 152 in the larger towns and 137 in England and Wales; it corresponded with the London rate of infant mortality. In the several towns this infant death-rate ranged from 92 and 94 in Dover and Bournemouth, to 187 in Ystradgynodwg, 188 in Hanley, 192 in Stockport, and 236 in Longton. Thus the rate of infant mortality in Longton, a pottery town, was in 1894 not far short of three times as high as it was in Dover and in Bournemouth. The health condition of Longton is conspicuously unfavourable, whether judged by the gross death-rate, the zymotic death-rate, or the infant death-rate; the death-rate among persons aged upwards of sixty years is also exceptionally high. It may be hoped that these valuable and uniform statistics now published by the Registrar-General for 100 of the largest English towns may serve to stimulate local interest in sanitation in some of those towns in which the value of public health is even yet not fully recognised and the true economy of sanitary expenditure is not appreciated.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

BRIGADE-SURGEON-LIEUTENANT-COLONEL MAJOR has embarked for Singapore to assume Charge of the Medical Staff in the Straits Settlements in succession to Brigade-Surgeon-Lieutenant-Colonel Hughes. Surgeon-Major Baker has been posted to Chatham; Surgeon-Major Morris to Alderney; Surgeon-Major Thomson to York; and Surgeon-Major Mulvany to Belfast. Surgeon-Captain Hughes has been transferred to Dublin, and Surgeon-Captain Forrest to Belfast. Surgeon-Captain Hickson has embarked for South Africa. Surgeon-Captain Wilson has arrived from the West Coast of Africa on completion of a tour. Surgeon-Lieutenant Milner has been transferred from Alderney to Portsmouth.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Major J. Anderson, Civil Surgeon, Bareilly, is appointed to the Visiting Medical Charge of the Pilibhit District, in addition to his other duties. The services of Surgeon-Colonel J. H. Newman, M.D. (Bengal), Residency Surgeon and Chief Medical Officer in Rajputana, are placed at the disposal of the Home Department. Surgeon-Captain W. R. Clark, Civil Surgeon, is transferred from Ferozepore to Mooltan. Surgeon-Lieutenant Bray, A.M.S., has been transferred from general duty, Poona District, to general duty, Aden. Surgeon-Lieutenants Evans and McDonald have been posted to general duty, Deesa District. Surgeon-Captain E. C. Hare, now employed as a Supplementary Medical Officer in Assam, is appointed to officiate as Civil Surgeon, Lakhimpur, until further orders. Brigade-Surgeon-Lieutenant-Colonel Arthur Luke Hackett, Madras (Surgeon, 2nd District), retires from the service.

NAVAL MEDICAL SERVICE.

The following appointments are announced:—C. Bradley to the *Herald*; J. P. Willis to the *Mosquito*; T. D. Halahan to the *Ripulse*; E. J. Fitch to Plymouth Hospital; and E. H. Meaden to the *Wildfire*.

ARMY MEDICAL RESERVE OF OFFICERS.

The undermentioned Surgeon-Captains, 5th Lancashire Volunteer Artillery (Southern Division, Royal Artillery), to be Surgeon-Captains: Henry Christopher Lampport, M.B.; James Arthur Rigby, M.D.

VOLUNTEER CORPS.

Artillery: 1st Kent (Eastern Division, Royal Artillery): Charles Macdonell Anderson, M.B., to be Surgeon-Lieutenant. *Submarine Miners*: *Royal Engineers*: Surgeon-Captain T. K. Dalziel, M.B., resigns his commission. *Rifle*: Galloway: David Duke Morro, M.B., to be Surgeon-Lieutenant. 4th Volunteer Battalion the Cheshire Regiment: Surgeon-Lieutenant H. Marriott, M.B., to be Surgeon-Captain. 2nd Volunteer Battalion the Oxfordshire Light Infantry: Surgeon-Captain G. A. Edsall resigns his commission. 2nd Volunteer Battalion the Duke of Edinburgh's (Wiltshire Regiment): Surgeon-Lieutenant H. J. Mackay, M.B., to be Surgeon-Captain.

THE LEVÉE.

The Services were represented at the Levée held on Monday last by the following gentlemen, who were presented to H.R.H. the Prince of Wales on behalf of the Queen:—Surgeon-Lieutenant Campbell Boyd, by Colonel S. B. Bevington; Surgeon-Lieutenant Eustace Maude Callender, Civil Service Rifles (12th Middlesex), by the Earl of Albemarle; Surgeon-Lieutenant E. P. Dickinson, 1st Volunteer Battalion the Northampton Regiment, by Colonel the Earl of Euston; Surgeon-Captain Joseph Fayer, Royal Horse Guards, by Colonel Brocklehurst; Surgeon-Major E. H. Fenn, C.I.E., Scots Guards, on being made a C.I.E., by Colonel W. J. Gascoigne; P. B. Handyside, M.B., Surgeon R.N., by the Medical Director-General of the Navy; Surgeon-Major Knott, 3rd Volunteer Battalion the Hampshire Regiment, on promotion, by General H.R.H. the Duke of Connaught, K.G., &c.; Surgeon-Major Leahy, I.M.S., by Sir Gerald Seymour Fitzgerald; Inspector-General W. H. Lloyd, M.D., R.N., on appointment as Honorary Surgeon to Her Majesty, by the Medical Director-General of the Navy; Surgeon-Major-General Markley, A.M.S., on promotion and on being made C.B., by the Adjutant-General; Surgeon-Captain Penny, Indian Medical Staff, by the Secretary of State; Surgeon-Captain J. R. Roberts, I.M.S., by the Secretary

of State; Surgeon-Lieutenant Austen-Smith, I.M.S., by the Secretary of State; Surgeon-Lieutenant-Colonel R. G. Tatham, 15th Middlesex R.V.C., by Colonel Chambers; Brigade-Surgeon-Lieutenant-Colonel William Daniel Campbell Williams, Principal Medical Officer, N.S.W. Military Forces, by Lord Carrington, G.C.M.G.; Surgeon-Captain E. Wilkinson, by the Secretary of State; Surgeon-Lieutenant P. Macleod Yearsley, 16th Middlesex (London Irish) R.V., by Colonel Ward, C.B.

NATIONAL VOLUNTEER MEMORIAL TO SIR JOHN C. BUCKNILL, M.D.

The connexion of Sir John Bucknill with the Volunteer movement is well known, and by many he is regarded as the originator and founder of the Volunteer force in Great Britain. In recognition of his services in this cause he received the honour of knighthood on the occasion of Her Majesty's seventy-fifth birthday; and a memorial in the form of a monument of grey granite and Portland stone, rising twenty-five feet in height, has just been unveiled at Exeter by the Duke of Cambridge. The memorial, which is surmounted by a regal diadem in stone, is erected on the site of the castle supposed to have been built by the West Saxons, which offered such a powerful resistance to the Norman Conqueror. The monument is embellished with a medallion of Sir John Bucknill, and on the west side is the following inscription:—"Erected to commemorate the formation in Devonshire in 1852 of the Volunteer force of Great Britain, as a consequence of communications from John Charles Bucknill, M.D., F.R.C.P., F.R.S., to the Right Hon. Hugh Earl Fortescue, K.G., Lord Lieutenant of the county of Devon and of the county of the City of Exeter. In recognition of his services to the Volunteer movement the honour of Knighthood was conferred upon Sir John Charles Bucknill by Her Majesty Queen Victoria in 1894."

THE MEDICAL SERVICES AND THE BIRTHDAY HONOUR LIST.

We congratulate the medical department of the navy on the birthday honour which has been conferred upon the head of their service and tender also our hearty congratulations and best wishes to Sir James Nicholas Dick, K.C.B. The public medical services are, with the foregoing exception, conspicuous by their absence in the list of birthday honours bestowed on this occasion in recognition of meritorious or long services in connexion with the army and navy. As regards those officers who have been so prominently brought to notice in connexion with the siege and relief of Chitral, a special gazette will presumably be published later. Surgeon-Major Robertson might well, we think, receive some titular distinction for his exhibition of ability and fortitude in the heroic defence of Chitral; and the valour, coolness, and self-abnegation displayed by Surgeon-Captain Whitechurch—about whom Surgeon-Major Robertson says "it is difficult to write temperately," and with reference to whom Captain Baird expressed a dying wish that "Whitechurch should not be forgotten"—fully entitle him to the Victoria Cross; that is the opinion of those who are best competent to judge as well as the opinion of his countrymen generally.

SMALL-POX IN CALCUTTA.

It has been stated that the recent epidemic of small-pox in Calcutta was of a severer type than that of 1865, but the *Times of India* says that this has no foundation in fact. In the epidemic of thirty years ago the mortality was over 3700, while the total mortality in the recent outbreak was a little over 1500 in the town and suburbs of Calcutta. With regard to typhoid fever and other diseases of an allied etiology, the report of the health officer of Calcutta, to which our Indian contemporary is indebted for its information, is far less satisfactory. It will be remembered that Dr. Simpson was not satisfied with the sewerage system of Calcutta, and succeeded in inducing the municipality to obtain the services of Mr. Baldwin Latham to report upon the subject, which he did. We do not find, however, that anything has been done to improve matters. The town is said to have been growing much more unhealthy of late years in respect of these diseases.

THE INDIAN VIEW OF THE OPIUM REPORT.

The report of the Royal Commission on the opium question seems to be regarded as likely, after all, to do great good in the way of putting a stop to further agitation on the subject, as far, at least, as all reasonable, unprejudiced people are concerned. The average Englishman will, it is believed,

look at Mr. Arthur Pease's signature as the most noteworthy of the eight that are appended to the report. The inquiry was generally regarded in India as perfectly unnecessary, and under the circumstances of the financial straits of the Indian Government unwarrantable, but the thoroughness and results of the investigation, and the fact that India has not had to pay for it, have produced a great change of opinion.

ARMY MEDICAL EXAMINATION.

An examination of candidates for thirteen commissions in Her Majesty's Army Medical Staff will be held at the Examination Hall, Victoria Embankment, W.C., on Aug. 2nd next and following days. Application for admission to the examination should be made in writing without delay to the Director-General, Army Medical Department, War Office, London, S.W.

Surgeon-Captain Alcock, of the Calcutta Museum, has been appointed Medical Officer to the Pamir Commission.

"Audi alteram partem."

"THE MIDWIVES REGISTRATION BILL."

To the Editors of THE LANCET.

SIRS.—In THE LANCET of May 25th you print a letter from Dr. Rentoul with what he appears to wish us to take as the opinion of counsel on the Midwives Bill, 1895. He published and gave wide circulation to a "counsel's opinion" on the last Bill, and the fallacies which formed the greater part of the opinion were promptly exposed and their arguments refuted by another lawyer. Many of the fallacies included in the original opinion are now again "trotted out"; but, as you observe, "'a case for counsel's opinion' is not the same thing as 'counsel's opinion,'" and it is open to grave doubt whether the "case" has ever received the sanction of a barrister. Some of the clauses contained in it, however, seem to call for remark from the authoritative way in which they are put forward. In the first place, it is not compulsory for a person to be on the Medical Register in order to "lawfully practise midwifery." On the other hand, the Midwives Registration Bill proposes to make it compulsory on all persons who wish to call themselves midwives or any similar name that they should be on the Midwives Register. Great importance is attached to this. It is not possible, apparently, to prevent people from practising as midwives, any more than people can be prevented from acting as medical men, and the next best thing is to prevent the confusion which will be caused by the assumption of any name like that of midwife. The Bill does not either "recommend the repeal of the Medical Acts," or does it "enact that a 'midwife' may practise midwifery without having studied either medicine or surgery." The Bill is intended to limit the practice of midwives to cases of a simple nature, and to place midwives under the restriction of rules of practice approved by the General Medical Council—neither limit nor rule is now applied to midwives' practice.

An old point is raised in Clause 5, that there is not sufficient material to train both pupil midwives and medical students. Dr. Rentoul distinguishes between these two classes, although he would have us believe that midwives can lawfully be placed on the Medical Register in spite of its being provided in Clause 4 of the Midwives Registration Bill, 1895, that a "certificate under this Act shall not confer upon any woman any right or title to be registered under the Medical Act, 1858, or the Acts amending the same."

In respect to the supposed deficiency in training material, special inquiries have been made at every training school for medical students in England, and the replies completely refute Dr. Rentoul's assertion. In addition, there has been no complaint at any time made by the authorities of the medical schools in respect to this point. Dr. Lovell Drage stated before the Select Committee, in 1892, if my memory serves me correctly, that St. Bartholomew's Hospital would suffer greatly in this respect. In reply to a query, the hospital authorities state they have an unlimited supply of maternity cases. As regards permitting men to be registered as midwives, perhaps Dr. Rentoul will remember that it was

especially pointed out by critics of one of the other Midwives Bills, that male unqualified assistants, if allowed to go on the Midwives Register, would be a very serious danger to the public and profession alike.

Dr. Rentoul makes an extraordinary number of incorrect remarks as to what is and what is not contained in the present measure. Provision is made for the supervision of midwives, for making rules for striking a midwife off the Midwives Register, for exceeding her duties, for judging her when accused of infamous conduct, for using instruments, for acting as a medical practitioner, and the other thousand-and-one inadvisable things a midwife may *now* do without let or hindrance, without pains or penalty, but which this Bill is expressly intended to meet. It is obvious—perhaps not to Dr. Rentoul—to say that if it were attempted to put into a Bill such as this one *all* the things a midwife might not do, even supposing such a disputable Bill to pass, any operation not specially mentioned would thereby be permitted to a midwife to perform. Dr. Rentoul objected to the word "operation," which appeared in another Bill (and he still quotes the clause in which the word appeared as showing the dire intentions of the backers of the Bill), yet he wishes to see the present Bill include a list of minor operations with implied permission to perform far more serious ones. Dr. Rentoul complains in his Clause 27 that no penalty is provided "should any person or persons other than those recognised by the Midwives Board lecture, examine, or grant a certificate to women which will qualify them to act as midwives," and yet in Clause 24 he says: "The Bill is not fair to midwives certificated and residing in Scotland and Ireland, as all such practising midwifery and using the title of midwife in England may be fined £5." I pass over the impossible conditions attached to the midwives in this clause to remark that the Bill is not intended to apply to either Scotland or Ireland, or to interfere in any way with either Scottish or Irish midwives.

I am, Sirs, faithfully yours,

F. ROWLAND HUMPHREYS.

South Hampstead, N.W., May 25th, 1895.

To the Editors of THE LANCET.

SIRS,—If in Dr. Pratt's letter in THE LANCET of May 25th we changed the words "woman," "midwife," and "midwifery" to man, doctor, and medicine, we might imagine ourselves to be reading a letter in opposition to the Medical Bill of 1858, and I doubt whether we should have approved the reasoning then. The arguments used for the one would apply also to the other. And why are we to be so fearful of the competition of the new midwife? I fear the opponents of this Bill do not credit the morals and methods of the medical profession, to which they belong, with a very high position or a very sure foundation if they believe that this competition will be injurious. We may be said to have been brought into competition with dentists and chemists, but, excepting in our pockets, I was not before aware that we suffered thereby. This has now become a public matter, and it behoves us as a profession to beware what arguments we use in discussing it. The public expect much of us, and we shall lose their help if we disappoint them and they see that we are influenced in our opinions and actions too largely by motives of sordid gain, and not by the highest considerations for the well-being of humanity. It is time now that we tried to come to some terms among ourselves as to what form we wish the measure to take, as otherwise there is a serious danger that the public may take it into their own hands and settle matters in a way that few of us approve. I have suggested elsewhere and in the columns of THE LANCET¹ that there is a middle course open to us, and the middle being proverbially the safest course I would ask both parties to this Bill to consider it. My suggestion is that the new registered midwives shall only be allowed to practise as the servants of some body such as a board of guardians, a nursing association, or a maternity charity, and that they shall there serve under certain stated regulations, including rules as to the advice and assistance of medical men. If we could agree on this salient point I believe the rest would be plain sailing.

I am, Sirs, yours obediently.

Freshford, May 23th, 1895.

CHARLES E. T. FLEMMING.

"ADENOID GROWTHS IN CHILDREN."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 25th there appears a paper by Dr. Eustace Smith on "Adenoid Growths in Children." He refers to that very interesting and obscure affection, infantile respiratory spasm, and, if I understand him correctly, states that in his experience it is always associated with, and due to, adenoid hypertrophy. In these cases he has "never failed to detect either actual vegetations or a thickened granular state of the post-nasal mucous membrane." He further asserts that if this unhealthy condition be remedied "the breath sounds soon recover their normal quiet." It is not my intention to enter into a discussion on the tempting subject of infantile respiratory spasm. Nearly all that can at present be said about it has been carefully stated by Dr. John Thomson in the *Edinburgh Medical Journal* of September, 1892. That it is a spasmodic and not a paralytic phenomenon is made certain by the periodic intermissions which occur in most cases, while the researches of Semon and Horsley make it highly probable that the stridor is due to cortical irritation. Adenoid vegetations are responsible for much evil and many symptoms, but it is extremely important that we should only ascribe to them phenomena which can be proved to be a direct result of the condition. To say that a child has some enlargement of the pharyngeal tonsil and at the same time laryngeal spasm proves nothing. In my own mind there still remain some doubts as to what is the normal size of the pharyngeal tonsil in young children. No doubt, however, Dr. Smith writes from careful observation, and I should, in conclusion, desire to ask him the following questions: (1) How many cases of infantile respiratory spasm has he observed? (2) How many were cured by treatment of the naso-pharynx? To establish a connexion the patient must have been immediately benefited by such treatment, for we know that the tendency in these cases is usually towards cure. I feel sure that a publication of the statistics on which Dr. Smith has based his statements will be looked forward to with much interest by many of your readers. I trust that he will see his way to giving them to the medical public immediately, if only in abbreviated form, for I feel sure that one always so accurate and careful would only have committed himself to the statements I have quoted on carefully recorded evidence.

I am, Sirs, yours faithfully,

Chester-street, Edinburgh, May 27th, 1895.

P. MCBRIDE.

CARAVAN HOSPITALS.

To the Editors of THE LANCET.

SIRS,—Seeing a notice in THE LANCET of to-day of a hospital caravan for infectious diseases, originated by Mr. James Wyllie, I think I ought to send you an account of a portable hospital for the same purpose which I arranged last summer for this district council. Like Mr. Wyllie, I procured a van fully sixteen feet long by seven feet wide, but, instead of using my van for the sick, I fitted it up as a kitchen, with dresser, drawers and cupboards, and an American cooking stove with hot-water attachment, so that there is always plenty of hot water for a bath or any other purpose. For the sick I have two Kadcliffe hospital tents with double walls and boarded floors, having four beds in each, so that I can accommodate eight patients; and I have a bell tent with two beds for the nurses, or nurse and servant. My hospital is fully equipped, and I think I have provided everything necessary for its purpose. When the hospital is not in use everything, excepting the floor-boards of the tents, which can be carried in an ordinary waggon, is stored in the van, so that there is no delay in transporting the hospital to any part of the district, and in two hours it can be erected and ready to receive patients. This hospital is, at the present time, in use at West Bergholt (about two miles from Colchester Railway Station), and I should be delighted to show it to any person who might desire to see it, on any day but a Wednesday, on his giving me notice of his visit. The tents are warmed by two paraffin stoves, and are very comfortable. During the first week they were in use the weather was, for a few days, very hot, and then suddenly we had a week of extremely cold days and nights. There was no complaint, however, of cold, but all the seven patients suffering from scarlet fever expressed themselves as being perfectly warm and comfortable. I send you by this post two copies of my annual

¹ THE LANCET, March 2nd, 1895.

report to this Council, and, if you look at page 8, you will find a short account of my portable hospital.

I remain, Sirs, yours faithfully,

Colchester, May 25th, 1895. JOHN W. COOK, M.D.

"THE PSYCHOLOGY OF ANÆSTHESIA."

To the Editors of THE LANCET.

SIRS,—I am much interested in Dr. Guthrie's critical remarks in THE LANCET of May 25th in answer to my letter in THE LANCET of March 23rd; but as there must be some 20,000 medical readers of your weekly journal in the British Isles and America I am surprised that Dr. Guthrie only has noticed my letter. There can scarcely be fewer than 1000 cases put under anæsthetics weekly, or say 50,000 a year in Great Britain, including midwifery and dental cases, and therefore, as I said before, the profession must be in possession of an enormous mass of evidence as to what patients say when so placed, and surely it must be important to discover what proportion of these 50,000 cases on recovery say that their impressions were that they had been out of their bodies.

In ordinary dreaming this impression is extremely rare, and the dreamers dream, not that they were out of their bodies, but that they fly with their bodies and get fixed in the dreadful grip of nightmare. Probably not fewer than 99 in the 100, on submitting to anæsthesia as a preparation for some operation more or less serious, are impressed with more or less anxiety and even awe, and if they dream, surely their dreams should be coloured by these sensations, and therefore it becomes the more surprising when we find that many of the dreams, instead of being terrible are celestial, and the visions are beheld "which eye hath not seen nor ear heard, nor hath it entered into the heart of man to conceive." Ordinary sleep and the condition of anæsthesia are not degrees of the same order, for out of the deepest sleep the subject can be awakened by the prick of a pin, but when under the influence of an anæsthetic the limbs may be amputated, and the patient simply smiles and dreams on. This condition is not one of sleep, but of trance, and trance is a condition outside of physiology to explain—a condition of the mind or soul independent of the body. The drowned man is altogether impervious to pain, because his soul or mind has been driven out of his body, and the patient whose lungs are filled with a foreign gas is in the position of a drowned man. But the drowned man may be resurrected by long-continued manipulations, and then he will often tell you, as in the case of those recovering from anæsthetics, that his dreams had been beatific. Dr. Guthrie says that my suggested method of experimental psychology would be that of "Philip sober appealing to Philip drunk," but I would answer that there is no proverb truer than *in vino veritas*. He when under an anæsthetic dreamed that "he was a great man driving in a grand carriage in the Row," but when the transcendental chemist, Davy, took anæsthetics he exclaimed prophetically, "Nothing exists but mind." The nature of the dream has a relationship to the character of the dreamer, and goes in the direction of showing that when we have shuffled off this mortal coil we only pass into a transcendental life and carry our individuality along with us.—I am, Sirs, yours truly,

Wimbledon-park, May 26th, 1895. GEORGE WYLD, M.D.

A SUMMER HOLIDAY FOR MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—Now that the holiday season is approaching, members of our profession after their hard winter's work will, in common with the general public, be contemplating where and how to spend their few weeks' well-earned rest. For many years past I have been in the habit of seeking a change in foreign climes, but last summer was persuaded to stay at home and try a tour round our "tight little island." Acting on this advice I joined the s.s. *Princess Louise* (one of Langland's steamers) Liverpool, on a Friday in July, and had what turned out a twelve days' perfect trip combining variety and rest—two essentials, I think, in a medical man's holiday. The places called at included Oban, Gairloch, Loch Eriboll (in Sutherlandshire), Aberdeen (with a drive up Dee side), Leith (with nine hours to visit modern Athens), Newcastle, Hartlepool, Hull, Southampton, Plymouth, Devonport, and Falmouth. The catering was of the best, the company most

agreeable, and the charge exceedingly moderate at £8 for the whole tour (including meals). I think that a holiday of this kind has only to be known to be appreciated by those requiring a change.—I am, Sirs, yours faithfully,
May 25th, 1895. FRANCIS W. GRANT, M.D., B.Sc.

INOCULATION FOR SNAKE-BITE.

To the Editors of THE LANCET.

SIRS,—The enclosed cutting has been copied, I believe, from a short note of mine appearing in the *South African Medical Journal* and the *Agricultural Journal* in February last. I shall be glad if you will direct my attention to similar practical observations, or even experiments, and their results—for, being cooped up in a country like this, I have little opportunity, except by reading your journal, of knowing what steps have been, or are being, taken in the direction my note suggests. It is my intention during next snake season to pursue a series of practical experiments with the view of endeavouring to discover whether it be possible to cultivate and attenuate a virus capable of inoculation, and rendering human beings safe from the effects of bites from at least one class of poisonous snakes hitherto considered so deadly in their character.

I am, Sirs, yours obediently,

S. CARTWRIGHT REED, M.D.

Herschel, South Africa, April 30th, 1895.

[ENCLOSURE.]

INOCULATION FOR SNAKE BITE.—Science has been making rapid strides in the discovery of poisons which counteract poisons, and diseases which are made to conquer themselves. The latest is the antitoxin for the cure of diphtheria, but something even later appears to be on the eve of discovery as a positive cure of snake bite, the following particulars are correct. Certainly they are worthy of investigation, and if the poison of the cobra can be cultivated and attenuated as to form a virus capable of inoculation and rendering human beings safe from snake bite, the boon would be invaluable. Dr. Cartwright Reed of Herschel says that two years ago a pointer dog was killing a cobra, and got bitten badly, with the usual severe symptoms of snake poisoning. Ammonia was used, and the dog recovered. A second dog was bitten, but milder symptoms followed. Both these dogs now go for snakes of all kinds, and get bitten about the lips especially. Last week one of these dogs got hold of a large hooded snake by the head, and the other by the body. The snake fastened upon the dog's lip in this case made it bleed, the other actually pulling the body in half. Five or six have been killed by them this season, but they seem both to be protected by the previous bites. A native was bitten twice in succeeding years. The first bite caused most severe symptoms of snake poisoning; the second bite, from a young fierce cobra, though apparently more severe than the first one, yet no bad symptoms, beyond a little local sore, followed. The doctor thinks that there must be something in the report by natives that when once bitten by a poisonous snake with marked symptoms of poisoning, there is no fear whatever from any subsequent bites.

"MEDICAL EVIDENCE AT INQUESTS."

To the Editors of THE LANCET.

SIRS,—I am obliged to you for inserting my letter of Feb. 22nd in THE LANCET of the 4th inst. and also for sending me a copy of your paper. All that seemed to trouble you before was my accepting a constable's evidence of a gunshot wound which, as I explained, was not correct, and now you raise a new point by stating that it would have been advisable to take the evidence of the medical man who first saw the wound. I have been candid with you and stated my reasons for taking the evidence of the medical man called at the inquest, and, being a lover of fair play, wish to know your reasons for making this new statement, and will thank you to insert them in your next issue along with this letter. Do you suggest that both practitioners should have been called, or that the one you refer to was the best to call? I think you should bear in mind that in this case there was no doubt as to the cause of death, and no two medical men could differ on that point, and it is the duty of coroners not to call more witnesses (medical or otherwise) than are absolutely necessary to assist in arriving at a proper verdict, otherwise they would be throwing the ratepayers' money away, and in many places the rates are too high already to indulge in this lavish expenditure.

I am, Sirs, yours faithfully,

H. W. MILLIGAN.

May 7th, 1895.

Coroner for Wigan.

* * In our original notice, under date Feb. 2nd, we expressed the opinion that the medical man who first saw

deceased should have been called in to give evidence. In a matter of violent death it is highly important that no facts should be missed that can possibly throw any light on the cause of death, and as to whether it was accidental, suicidal, or homicidal. Our text-books lay down that all surrounding circumstances and conditions should be observed and noted by the medical man as soon as he is called to the case, and to this we fully subscribe. Our information led us to understand that the constable's evidence as to the nature of the lesions was taken. If Mr. Milligan says this was not the case we accept his statement without the least reserve, and express regret that our remarks should have misrepresented the facts. We stated that the family medical attendant was called, but we understood that it was done with a view of throwing light on the probable state of mind of the deceased at the time of his death. In Mr. Milligan's letter published in our issue of May 4th he informed us that the practitioner in question arrived shortly after death and examined the wound, and that he gave evidence thereon at the inquest. Under these circumstances it must be conceded that Mr. Milligan took a reasonable course, and we regret that our notice should have conveyed an intimation to the contrary. At the same time, we cannot but think it would have been better to have taken the testimony of the medical man who first saw the deceased.—
ED. L.

COLLECTIVE INVESTIGATION IN LUNATIC ASYLUMS.

To the Editors of THE LANCET.

SIRS,—At a recent meeting of the Medical-Psychological Association it was decided to collect facts by pursuing in lunatic asylums the method of collective investigation. May I through your columns ask those medical officers of asylums who are willing to coöperate in the scheme to communicate their willingness to me?

I remain, Sirs, yours truly,

Catford, S. E., May 26th, 1895.

CHAS. MERCIER.

THE SWEATING OF MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—Again and again some member of the profession returns to the charge in the battle against the degrading impositions which are forced upon us, and yet again the only answer of our representatives in the General Medical Council is a feeble *non possumus*. That it would be difficult and perhaps dangerous to interfere with the private arrangements between medical men and their patients may be taken for granted, but in public or semi-public appointments, not in the hands of medical men but run by syndicates and societies for their own profit, surely there would be no difficulty. All the General Medical Council has to do is to declare that such arrangements are "infamous in a professional respect," as, indeed, they are, whether the Council think so or not. The hiring of medical men on such terms is slavery in the specious guise of semi-charity. Cork has the courage of its opinions and has led the vanguard; will our somewhat weak-kneed Council come in at the last when the battle is almost won and claim the credit? Council or no Council, there are many of us who will go on agitating until some measure of reform of such glaring abuses can be gained, and every day some fresh recruit is enlisting for the fight for decency and respectability, if nothing more, in our financial relations with the public.

I am, Sirs, yours obediently,

May 27th, 1895.

J. B. PIKE.

"THE LONDON AND MANCHESTER INDUSTRIAL ASSURANCE COMPANY, LIMITED."

To the Editors of THE LANCET.

SIRS,—We have weekly gained evidence as to the workings of this company as compared with charitable provident dispensaries, clubs, &c., and the answers to my queries of March last have been clearly and lucidly evolved. What can be done to remedy the evils and abuses which exist

beyond dissociation from such by medical men individually? The medical practitioner is handicapped against charitable provident dispensaries and medical aid companies by reason of the restriction of the staffs of the former to a few, together with the just prohibition to advertise and tout. Under these existing circumstances he must join the company or else lose ground. But such should not be allowed to be the case. Organisation of the profession in these matters is required (Dr. Humphreys suggests a central coöperative medical association), but the General Medical Council through its representatives ought to safeguard the profession from its abuses, whether existing in hospitals, charitable provident dispensaries, medical aid companies, or commercial undertakings, and by their power, with the aid of legislation, rectify the existing abuses and degradation of the profession which are becoming so intolerable. We hear of coöperative drug stores, but not of coöperative legal associations; then why of the arts of medicine and surgery? There requires to be a thorough search into the whole matter and proper regulations should be made to meet the requirements of the times in which we live, and no one would be happier to assist in it than myself.

I am, Sirs, yours faithfully,

May 22nd, 1895.

INQUIRER.

"SMALL-POX IN CALCUTTA."

To the Editors of THE LANCET.

SIRS,—In reply to Dr. Gramshaw's inquiry in THE LANCET of May 25th, vaccination in India is not compulsory, neither would it be possible to make it so owing to the style of habitation of the natives and the caste prejudice of many of them regarding the females of their families. I do not know that any caste or creed look upon either small-pox or vaccination with particular disfavour. The former they certainly consider to be a form of wrath of one of their many gods. The difficulty in making vaccination compulsory exists in the fact that the majority of the poorer classes live in small mud huts, crowded closely together, and that they are constantly changing their location, no small number of them having no home at all, but simply sleeping and eating when and where convenient, and performing their scanty toilets in the same style. The registration of them would be about as easy as undertaking to separate the sexes of an ant-hill. Native servants will come to their daily household duties, look after one's children, clothes, and washing, and cook one's food, though all the members of their household are down with the disease. This is no doubt partly due to fear of losing their situations, but principally to the utter indifference of the native mind to the danger of any infectious disease.

I remain, Sirs, yours faithfully,

May 29th, 1895.

L.R.C.P.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday Fund.

YEAR by year the amount asked for in the contributions to this fund grows and swells in degree. £13,000 is the sum which the managers have put down this time for the public to realise. So far the payments into the bank justify the sanguine expectations of the promoters of the movement. Thus, on Tuesday last the total received at the bank was £10,809 16s. 10d., as compared with £9692 13s. 1d. at the corresponding period of last year. If this increase is maintained up to the time of the closing of the account it may be hoped that the contributions will reach the sum asked for by those who have devoted so much time and energy to the project.

Death of Mr. Hugh Thomas.

The lamentable accident which resulted in the death of this popular practitioner has given rise to some discussion on the lighting of vehicles at night. If cyclists are required to show lights after a certain time in the evening it is argued with some degree of force that it is quite as necessary that lights should be attached to all vehicles. It is true that Mr. Thomas was slightly deaf, and probably did not hear the approach of the butcher's cart which knocked him down and caused the fatal injuries he received; but had the vehicle shown lighted lamps it is possible that the use of his eyes might have atoned for any slight defect in his ears. At all

events, the subject is worth the consideration of the authorities with a view to prevent the occurrence of such accidents.

Gift of a Sanatorium.

A munificent offer has been made by Colonel J. H. Wilkinson and accepted by the committee of the Birmingham and Midland Counties Sanatorium. It consists of the building now known as the Royal Hotel, Sutton Coldfield, the value of which is estimated at £15,000. At present Colonel Wilkinson is the treasurer of the sanatorium committee, and so has a thorough knowledge of the requirements of a large artisan population. The hotel is splendidly situated, well built, and surrounded by beautiful scenery. Of the value of such a gift it is hardly possible to form an adequate idea; future generations will reap enormous benefits by such an institution, and immense gain will be realized to the health and comfort of the poorer classes.

"House Nerves."

The local press has contained an animated discussion on this subject. There appear to be two sides to the question, but in the present controversy the male part of the public here evidently got the worst of it. No doubt each sex looks at the subject from its own point of view, but the conditions are so complex and the opinions so various that it is impossible to form an estimate of the actual truth. Divested of all the acrimony and bitterness of debate, it is possible that there is an element of truth on both sides, and that, as usual, the mean is to be deduced as the most likely solution.

The Endowment of Research Scholarships at Mason College.

A notice has been issued by the registrar of the College concerning three Priestley scholarships in chemistry, two Bowen scholarships in engineering, and one in metallurgy, which have been founded by the late Mr. T. Aubrey Bowen of Melbourne. These scholarships are intended to encourage and afford facilities for the higher study of these subjects in Mason College, where they are tenable for one year with the possibility of renewal at the discretion of the council of the College. The annual value of each is £100. Although naturally good work done at Mason College will be regarded as a specially favourable qualification, the council have generously thrown all the scholarships open to general competition. The first award will be made in September next, and all particulars may be learned on application to the secretary of the College.

May 28th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Cottage School Homes for Pauper Children.

THE Chorlton guardians are making an important and interesting departure from the barrack system of dealing with pauper children. They have adopted plans for cottage homes and schools for about 300 children at Stryal, a pleasant district in Cheshire several miles from the city. The set of designs selected out of eighteen sent in for competition is estimated to cost £26 500. The buildings and playgrounds &c. will occupy an area of about eighteen and a quarter acres. The architect, Mr. J. B. Broadbent, has eliminated whatever would savour of institutionalism, and arranged the homes, the grounds, and everything connected with the general plan as far as possible after the fashion of a country hamlet, with as much freedom to the children as if they were living with their parents. There will be double roads with the recreation grounds between, placing the houses 125 yards apart. They will run from north-west to south-east parallel to each other, and the houses will have a southerly or south-westerly aspect. The children will be encouraged to healthy exercise and play, as the recreation grounds will be close at hand, while supervision will be easy, as the officers in their houses can see all that takes place. There will be a superintendent's house and board-room, administrative offices, workshops, bath, &c. On one side will be the boys' houses, and those for the girls on the other, and at the extreme end of the site a cottage hospital. The boys' playground between the two roads will be 100 by 130 yards, and the girls', 100 by 60 will be behind the school. The water-supply is said to be good. The drainage will be good, but the only practical outfall will be to a sewage farm on the estate. The whole

establishment is to be lighted by electricity, for though the first outlay is somewhat greater than for gas the cost of management is much less. The details as to living-rooms, dormitories, &c., seem to have been carefully considered, and it is to be hoped that the attempt to bring up these poor children with less of the atmosphere of pauperism about them will succeed as it deserves to do.

Dr. Niven on Jewish Mortality.

Manchester has a large and increasing population of working-class Jews, chiefly congregated in one part of the city, and one of the most useful of the benevolent institutions of that community is the Jewish Ladies' Visiting Association, which "through personal intercourse and sympathy endeavours to raise the status of those to whom the community must mainly look for its future development and strength." In moving the adoption of the report at the annual meeting held the other day Dr. Niven, our medical officer of health, said it was a most wonderful thing that year after year and quarter after quarter the mortality amongst the Jewish people of the poorest class was so very much below that of the population surrounding them, being in some cases not more than half that of the poorer districts of the city generally. It was remarkable "to find in the lower part of Strangeways a death-rate such as might compare with the healthiest cities in Great Britain." It was by no means easy to say to what it was due. Last year he thought it might be due to the fact that Jewish mothers stayed at home and nursed their children more carefully than was the habit of a great many of the industrial workers of our own people, but he could not find anything to show that this was the chief cause of the low death-rate. The comparative lowness of the mortality was not greater in children than in adult life. General causes must be at work, and as the first and chief he would suggest temperance. "Dirt was a great cause of disease, and it was an excellent thing that attention to personal cleanliness had been one of their religious observances. Then again they took very stringent precautions against the consumption of impure meat, and, what was even more important, they insisted upon getting pure milk." Dr. Niven made a serious charge, which I fear was justified, in saying: "A great many of the dairies of Manchester were mere cowsheds and were in a most disgraceful condition, and the milk sold among the poorer classes was often a means of spreading disease," and he advised that it should be boiled before use. "Another thing that would contribute to their health was the fact that even the poorest of them contrived to get good food and to eat well and heartily."

Light Sentences for Savagery.

Either the law is strangely lenient or some of its administrators consider that brutal assaults should be dealt with tenderly. At the City Police-court the other week two women and a youth were charged with assaulting a girl. One of the former had a grudge against the girl's sister and sought vicarious revenge, so, going up to her as she was sitting on her door-step, she said: "If I can't take it out of your sister I will take it out of you." The girl was thrown to the ground and savagely kicked and struck. Then the youth joined in and hit her while down on the right eye with the buckle end of his strap, bursting the eyeball and destroying the sight. As one of the local papers says: "We want something like the old Mosaic law, 'an eye for an eye, and a tooth for a tooth,' in order to deal with the 'scuttling spirit.'" The magistrates on the bench—whose names are given in the paper—evidently do not think so. One of the women had already been convicted several times—was therefore a well-known character—and deserved the severest punishment, so she was fined one guinea. The other female fury, who dragged the girl off the door-step and threw her down, was fined half a guinea; while the gentle youth who burst her eyeball was sent to the workhouse for a week. The Manchester workhouse is conducted most humanely, with every consideration for the comfort of the inmates, so it may be hoped the poor fellow will survive his sad fate. No doubt the tender hearts of the magistrates were wrung with anguish when duty compelled them to punish with such sternness these estimable members of Ancoats society who had only kicked a girl—and these women can kick,—struck her, dragged her off her own door-step, burst her eyeball, and left her bruised and horribly disfigured for life. If this is a sample of even-handed justice of the modern type it would be almost better to go back to the times when the victims of such brutes would have received

some of the sympathy now lavished on our criminals of both sexes. The sentences were said to have caused amazement in court.

Imprisonment for exposing Bad Meat.

A butcher of Salford was summoned on May 22nd, at the instance of the health authorities of Salford, for exposing for sale a large quantity of beef, mutton, &c., which was unfit for food. Mr. Paget, the medical officer of health, said some of the meat was quite green and putrid. The defendant said the bulk of it was intended for the "bone man," but the stipendiary magistrate evidently did not believe this, as he said it was one of the worst cases that had ever come before him, and he could not impose a fine, but the defendant would be sent to prison for six weeks. The poor Jews of Strangeways are saved from the danger of being poisoned by bad meat, but the poor Christians of Salford will have to be careful. The salutary punishment of this man may perhaps be somewhat deterrent to the brotherhood of "slink butchers," and it is in marked contrast with the mistaken leniency of the sentences on the assailants of the girl in Ancoats.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

University of Durham College of Science Concert.

THE Choral Society of the College of Science gave its third annual concert in Newcastle-upon-Tyne on May 21st. The programme consisted of Cowen's "Rose Maiden" and Mendelssohn's "Come, let us sing," both of which were very efficiently rendered. The new song, "Salve Boreale Lumen," written by Professor Dufl and set to music by Professor Terry, both of the College of Science, for the Durham undergraduates, was sung for the first time publicly with great spirit, and was much appreciated by the large and fashionable audience. I give the first stanza, that your readers may appreciate the swing and go of the verse:—

"Salve boreale lumen
Resplendentis Anglie!
Salve venerandum nomen
Veteris Dunelmie!
Alma Mater, ave! salve!
Floreas in secula!"

The concert was a most successful and enjoyable one and reflected great credit upon the society.

Durham University Sports.

The University athletic sports were on May 23rd for the first time held in Newcastle-upon-Tyne, and the afternoon being bright and fine the meeting was a great success. Mrs. H. P. Gurney, the wife of the new principal of the Durham College of Science, distributed the prizes to the successful competitors. Medicine, science, and arts were all represented. The success of the meeting was due greatly to the President of the University of Durham College of Medicine Athletic Club, the popular Professor of Anatomy, Dr. Howden, and to the secretary of the athletic sports, the Rev. E. R. T. Biggs, to both of whom, as well as to Mrs. Gurney, a hearty vote of thanks was given. The music was supplied by Mr. R. Smith's military band, and contributed in no mean degree to the enjoyment of the day. In future time sports will be held alternately in Newcastle and in Durham. It is rumoured that the constabulary grounds, upon which, by the kind permission of Captain Nichols, the sports were held, are to be sold for building purposes. Here is an opportunity for some philanthropist to purchase, for the good of the students, an excellent recreation field.

Newcastle-upon-Tyne, May 28th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Alkali Works in Scotland.

IN his last annual report to the Secretary for Scotland, Mr. A. E. Fletcher, the chief inspector of alkali works, notes that there have been no prosecutions in Scotland under the Alkali Act during the past year. He attributes this largely to the result of continual inspection and to the "critical eye"

of the Government officer. Whilst the legal limit of hydrochloric acid gas permitted to escape from an alkali works is 5 per cent. of that produced, the average from all the works during the year has been only 2.81 per cent. The amount of alkali produced in Scotland is gradually decreasing, and the same is the case in England as regards the Leblanc soda process. This is due in part to the competition of other countries, and partly to the success of the ammonia process; the coalminers' strike, by increasing the price of coal, having also been a recent influence in depressing the soda industry. Mr. Fletcher also refers to the new process of Mr. Donald for the manufacture of bleaching powder from chlorine produced by the action of nitric upon hydrochloric acid. He regards this as being still in the experimental stage.

Teachers' Guild, Glasgow.

At a recent meeting of this guild a lecture was delivered by Dr. Elizabeth Pace upon the Conditions of Healthy Study. The lecturer insisted upon the necessity for physical training, and recommended the use of the Swedish system of exercises.

The New Deputy Commissioner in Lunacy.

Dr. J. F. Sutherland, until recently medical officer to the prison in Glasgow and secretary to the Scotch Departmental Committee dealing with the question of habitual offenders, appeared on May 21st before the Lord President of the Court of Session and took the oath of secrecy on his appointment as Deputy Commissioner in Lunacy.

Medical Appointments.

The Largs Commissioners have appointed Dr. J. Miller to be burgh medical officer, and Mr. Syme to take charge of the hospital for cases of infectious disease. Dr. McLachlan and Dr. Mitchell have been elected medical officers under the Cardross parish council; and Dr. Black Morrison and Dr. Moore have received similar appointments from the Ayr parish council.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Irish Academy.

AT a general meeting of the Academy held on the evening of May 27th Professor D. J. Cunningham, F.R.S., read an interesting paper on Head Injuries inflicted by Stone Weapons. The paper was illustrated by a series of crania from the valuable collection made by Dr. Haddon when he visited some years ago New Guinea and Torres Straits. The natives of New Guinea are continually engaged in blood feuds and inter-tribal warfare, and as it is their custom to preserve as trophies the skulls of their enemies, just as the Indians do their scalps, a craniologist and collector has special opportunities there, of which Dr. Haddon seems to have very fully availed himself.

The Sir Patrick Dun's Hospital Bazaar.

The mammoth bazaar in aid of the funds of this, the Trinity College hospital, has been, as far as can yet be known, a conspicuous success. It was open during the day and evening for all the past week, and the returns show that during that time no less than 75,000 persons passed through the turnstiles.

A Bacteriological Institute in Dublin.

IN reply to a question recently asked in the House of Commons by Mr. McNeill as to whether applications from various quarters had been made to the Irish Local Government Board to take the necessary steps to establish a Pasteur Institute in Dublin, Mr. John Morley said he understood that the boards of guardians of a large number of unions in Ireland had adopted a resolution of the nature referred to, and that the Local Government Board was now collecting information as to the amount expended from the poor rates in sending poor persons to the institute in Paris for treatment, and that "his honourable friend might rest assured that the whole matter would be carefully considered." Now a strong feeling exists among the educated public and among medical men in Ireland that "when the whole matter" is being "carefully considered" some steps may be taken to establish and endow a bacteriological institute in Dublin. There is at least one eminent pathologist here who devotes all his time to that subject, and it would obviously be to the advantage of the public and of the profession if a

suitably endowed and properly equipped laboratory was established. It has been done, as we know, recently at Leeds, while at Liverpool University College a new pathological and bacteriological laboratory was formally declared open on May 18th.

The Rotunda Hospital, Dublin.

A very successful "At home" was given in the grounds of this hospital on Friday last, by the Master and Mrs. Smyly.

Royal College of Surgeons in Ireland.

An examination for the Fellowship, under the new regulations, has been held during the past week. In Grade I., open to surgeons of less than ten years' standing, three candidates presented themselves for the primary examination, of whom one was rejected in practical histology, another failed in practical anatomy, while the third passed the primary and afterwards presented himself for the final examination. There were seven candidates for the final examination, four of whom satisfied the examiners and were formally admitted Fellows of the College. They were Messrs. Cox, Finlay, Greer, and Trehwella.

The Ligoniel Sewerage.

At a meeting of the Belfast board of guardians held on May 21st one of the members reported that the grazing lands from the Fourth River Bridge to Ligoniel were not provided with water for cattle, except sewage matter from privies. The milk of these cattle, he said, was delivered to the better parts of the city. The chairman said the guardians should provide the water, and it was decided to appoint a committee to visit the place and report to the board. There can be no question that a new sewerage scheme is urgently needed for Ligoniel as well as a water-supply; both are at present greatly wanted. The former could be best supplied by an extension of the city boundary so as to embrace Ligoniel and the connexion of the sewerage of that place with the city system. As to the water-supply, a new one must be made, as the village is too high to be supplied by the Belfast Water Commissioners.

Royal University of Ireland: the Examinations for the Degree of M.B.

At the medical degree examinations of the Royal University Mr. James A. Craig was awarded a first class and an exhibition of £40, and Mr. Thomas Houston, B.A., a second class and an exhibition of £25. Both candidates are Belfast students. No other honours in the M.B. examination were awarded.

Medical Appointments, Belfast.

At the Belfast Hospital for Sick Children Dr. T. S. Kirk has been appointed assistant surgeon, and Dr. W. Steen assistant physician. A new departure was made in the method of election. No candidates were proposed, and the election was by ballot.—Dr. Lyness has been appointed resident physician in the Union Hospital, Dr. Patrick has been transferred to his place in the Union Infirmary, and Dr. Gibson succeeds to Dr. Patrick's place.—Dr. Whittaker has been elected extern house surgeon to the Royal Hospital.

The Belfast Hospital for Sick Children.

The board of management are at present making considerable structural alterations in this hospital, involving a cost of £700, to enlarge principally the extern department, where the number of patients attending has been steadily increasing. Last year there were 11,438 new extern cases.

The Dundalk Workhouse Drainage.

The defective sewer from the workhouse has now been closed and the sewage is being pumped into a disused quarry on the grounds. At a meeting of the board of guardians held in Dundalk on May 27th letters were read on behalf of Lord Roden protesting against the sewage being permitted to escape into the Rampart river, and from the Great Northern Railway against the pollution of a stream running through their works and workmen's houses which, it is alleged, was contaminated by sewage escaping from the sewer. No reply has as yet been received from the Local Government Board to the guardians' resolution asking for a sworn inquiry into the causes of failure of the sewer, which cost over £1000 three years ago. A general meeting is to be summoned to deal with the question of the construction of a new sewer.

Belfast Royal Hospital.

At the quarterly meeting held on May 27th it was reported that 476 intern patients had been treated during the year, 240 medical and the remainder surgical, while during the

same period there were 5144 extern cases. To the end of April the receipts had been £5380 19s. 6d. and the expenditure £6290 7s. 1d., being an excess of expenditure over receipts of £909 7s. 7d., but as the year ending Aug. 31st commenced with a balance of £199 17s. in favour of the hospital the actual debt at the end of April was £709 10s. 7d.

The Maintenance and Care of Harmless Lunatics at Millstreet.

The decision of the Lord Lieutenant that the governors of district lunatic asylums are primarily responsible for the maintenance of harmless lunatics has led to numerous discussions at various meetings of boards of guardians. The Millstreet board by a large majority decided that it is desirable to amalgamate their union with adjoining unions, and thereby escape large establishment charges for the maintenance of comparatively few paupers, and they consider the present a favourable opportunity for amalgamation, as they hope their buildings may be purchased for the purpose of converting them into an auxiliary district lunatic asylum. The Fermoy guardians, too, have been considering what they had best do with the harmless lunatics in their workhouse. Colonel Johnson, who is also a governor of the Cork Asylum, recommended the guardians, in the interests of these poor afflicted patients, to send them to the asylum, where he considered they would be better looked after, and he gave some interesting statistics with regard to the chargeability of such cases. He pointed out that in the Fermoy Union the cost of maintenance is £16 14s. 4d., and that the cost in the District Asylum would be £20. He further added that half of the £20 is paid by Government, the remaining half being paid by the occupiers—that is to say, practically by the farmers. On the other hand, half the £16 14s. 4d. is paid by the landlords and half by the tenants. Apparently the latter arrangement is preferred by the guardians, as they decided to look after their own harmless lunatics. Dr. Magner, *ex-officio* guardian of the Cork Union, considers imbeciles and idiots ought not to be removed to the lunatic asylum, as he believes it would be better for them mentally and physically to be kept in the Cork workhouse.

The Battle of the Clubs at Cork.

At a meeting of the council of the medical profession of the city of Cork held on May 22nd it was unanimously resolved: "That we cordially approve of the action of the Inverness medical profession in the stand they are taking against the absurdly low rate of society remuneration hitherto paid in that city; that we wish them every success in their effort, which we hope will be extended to every city in the United Kingdom, to raise the rates paid to medical men and to discountenance in every way the admission of unsuitable members to the societies; that a copy of this resolution be forwarded to Dr. Munro Moir (secretary to the Inverness Medical Society) and the medical journals."

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Intravenous Mercurial Injections in the Treatment of Syphilis

M. ABADIE¹ reminds us of the hesitation prevailing amongst many practitioners in instituting mercurial treatment before secondary symptoms have in a given case declared themselves. When, moreover, syphilides appear most practitioners (in France, at least) limit their endeavours to counteract the inroads of the virus by prescribing an altogether too brief course of green iodide of mercury. The application of this method is, indeed, generally productive of a cure which is, unfortunately, but too frequently only apparent. M. Abadie would have the profession more far-seeing, and this one can understand in an ophthalmologist who is so often called upon to combat tertiary affections of the eye, such as choroido-retinitis, and atrophy of the optic nerve either simple or associated with medullary lesions. Neuro-pathologists meet with numerous cases of cerebrospinal disease in patients who, afflicted with syphilis ten, fifteen, or twenty years ago, have received only inadequate treatment. M. Abadie states that these grave tertiary affections of the eye and nervous system are habitually met with in individuals in whom the primary and secondary lesions have been mild and who have, consequently, been subjected

¹ Société Française de Dermatologie et de Syphiligraphie, April 19th, 1895.

to a treatment which one may qualify as theoretical. Those persons who, on the contrary, have, on account of the severity of the early symptoms, been treated seriously and for a lengthened period generally escape these dangerous tertiary affections. M. Abadie would treat every case as soon as the diagnosis is made, not with the green iodide, but by means of inunction, or preferably with subcutaneous injections of a soluble mercurial salt. These injections conducted intermittently after this plan—one month's treatment followed by a rest of ten or twelve days—he continues for at least six months. Should tertiary symptoms appear, recourse must be had once more to the hypodermic plan. If the retrocession of the symptoms be not procured rapidly, the subcutaneous must be replaced by intravenous injections, which are much more efficacious. With a Debove's iride-platinum needle and a perfectly aseptic syringe no apprehension need be entertained as to the safety of this method, which is painless. The solution used by M. Abadie is thus composed: cyanide of mercury, 1 gramme; distilled water, 100 grammes. Of this solution one gramme (one centigramme of the salt) is injected every other day for twenty days, this being followed by a rest of fifteen days, and this again by a resumption of the injections if necessary. A ligature is placed around the upper arm, and, the skin and glass syringe being previously well disinfected, the solution is introduced into a prominent vein of the bend of the elbow, the ligature being removed directly the needle has penetrated into the vein. The proceeding is painless, and the patient returns immediately to his work.

Comparative Number of Medical Students in Italy, Germany, and France.

From figures recently published it would appear that the number of medical students studying in the twenty-one universities of Italy during 1894-95 is 19,043. These numbers are very unequally distributed amongst the universities, 3697 being found at Naples and only 87 at Milan. Altogether there are in Italy 61 students of the healing art to 100 000 of the population, the corresponding proportion in Germany and France being 63 and 57 respectively.

Successful Treatment of Puerperal Septicæmia with Anti-streptococcic Serum.

Dr. Jacquot² of Creil, near Paris, reports an instance where Roger and Charrin's serum was successfully applied in combating the above-mentioned dangerous condition. After quinine and intra-uterine douching had been unsuccessfully tried, the temperature reaching 40.8° C. (105.4° F.), 30 c.c. of the serum were injected. In a few hours the temperature had descended to normal. Two more injections were given, and the woman appeared to have quite recovered. Three days later, however, the patient's mother fell ill with erysipelas of the face, and this seems to have determined in the *accouchée* (two days later still) rigor accompanied by a temperature of 104° F. Three days after this relapse a fresh injection of the serum was practised, the temperature falling quickly to normal. From this time forward recovery was uninterrupted. This case serves to illustrate the prompt antithermic action of the serum and the intimate connexion existing between puerperal fever and erysipelas.

The Cold Bath in the Pneumonia of Children.

M. Comby³ calls attention to the excellent effects yielded by balneotherapy in the pneumonia of quite young infants. Applied at a temperature of 25° or 20° C., according to age and circumstances, the cold bath is most serviceable in reducing the temperature, restoring lost tone, and slowing the pulse and respiration. Chemical antithermic agents, such as antipyrin, quinine, &c., are generally useless and may be dangerous. In his wards M. Comby gives cold baths to all his little pneumonic patients whose temperature exceeds 39° C. (102.2° F.) and whose hearts are not diseased. Quite recently he had an opportunity of noting the good effects of this treatment in a little boy affected with influenzal pneumonia of the right apex, uninfluenced by ordinary antithermic drugs. M. Comby adds that baths of 25° C. are quite well supported by even very young infants. M. Sevestre states that the application of the above method of treatment determines the onset of the crisis on the fifth instead of the seventh day and so materially shortens the duration of the disease. M. Rendu also characterises the cold bath treatment as the best

means of obtaining prompt defervescence in the pneumonia of adults. M. Siredey informs us that at the Aubervilliers fever hospital he has derived great advantage from the employment of cold baths in the treatment of broncho-pneumonia consecutive to specific fevers, and M. Le Gendre made a statement corroborative of their efficacy in all congestive complications of eruptive fevers. Professor Hayem says that at the Hôpital St. Antoine the most fatal disease of all is pneumonia, and that eighteen out of twenty of these patients are "alcoholics." During the first two years, 1879-1880, of his physicianship at that hospital he lost 50 per cent. of these cases. He then instituted the cold bath treatment and the mortality fell to 27 or 28 per cent. For some time past this mortality has further diminished (to 8 or 10 per cent.), but this improvement he ascribes to a new special treatment he has devised for the benefit of these alcoholic patients. Employed in the *crèche* attached to his wards, Professor Hayem finds the cold baths more powerful for good against pneumonia than when used for adults.

M. Pasteur.

It is stated that M. Pasteur, having been sounded on the subject, has replied that he cannot be induced to accept a German decoration.

May 25th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Reform of International Congresses.

IN the last number of the *Quarterly Journal of Public Health* (*Vierteljahrsschrift für Öffentliche Gesundheitspflege*) the editor, Dr. Pistor, in an article on the Hygienic Congress in Budapest, energetically argues that the general management of medical congresses requires improvement. His principal complaint is that the entertainments, such as formal dinners, evening parties, invitations to visit industrial establishments, &c., consume a great part of the time which ought to be given to the meetings. This, he says, was the case in London in 1891, and also in Rome last year, but far more conspicuously in Budapest, where he was sure that a large proportion of the native members only attended the Congress in order to take part in the festivities. The best way will be to discontinue all official entertainments. Visitors who desire sumptuous festivities should provide them at their own expense, and ought not to expect the municipality and townspeople to lay out money for this purpose. Many towns are, in fact, unwilling to receive international congresses on account of the heavy expenses connected with them. In Dr. Pistor's opinion the committees ought only to provide a suitable building for the sittings, and in the smaller towns sufficient accommodation for the temporary excess of visitors over the usual number of strangers. Congress committees, however, seem to be proud if their visitors surpass in number those of any former meeting, and it has accordingly become quite usual for them to endeavour to attract foreigners by announcements in the ordinary newspapers. This, as Dr. Pistor remarks, far exceeds the limits which committees ought to observe. It would be quite enough if early intimation were given in the medical press of the date at which the congress is to be held, and the principal subjects which will be discussed. In this way only those will attend who have a real interest in the work of the congress; not the number but the scientific renown of the members is the criterion of its importance. Another source of difficulty is that the number of papers to be read is usually far too great. The subjects of discussion ought to be fixed by the executive committee, and the introductory addresses should be delivered by previously selected speakers. In the subsequent discussion everyone ought to have ample opportunity of expressing his views, and in the event of there being sufficient time after the discussion of the official subjects other questions might be taken up. The present custom of allowing everyone to speak on any subject, and often on matters of no actual or general interest, causes much loss of time and induces many leading men to abstain altogether from attendance at congresses. The number of sections should also be restricted. Dr. Pistor is confident that he is in agreement with the great majority of medical men and adds that also in France the reality of these inconveniences is fully

² Société de Biologie, May 11th, 1895.

³ Société Médicale des Hôpitaux, May 17th, 1895.

recognised, as M. Vallin, the chief medical officer of the French army, had expressed nearly the same opinion. No doubt the reforms suggested by Dr. Pistor would make medical congresses what they ought to be—meetings for professional work and not for social entertainment.

Penalties for Ethical Misdemeanours.

In several of the Confederated States of Germany there are medical boards elected by all the practitioners of the country, their duty being to act as representatives of the profession in matters which come before the Government. They are wont to be consulted if the Government intends to alter laws affecting the profession or if important questions of public health arise, and on other occasions when the authorities wish to hear the opinion of independent medical men in addition to that of their permanent medical officials. But their principal duty is to form courts of discipline (*Ehrenrath*) if any controversy in matters of ethics happens to arise between medical men, or between practitioners on the one side and the public on the other. For this purpose they are authorised to compel the attendance of the disputants and to pronounce judgment in the case. They have, however, no punitive authority, but can only withdraw from a medical offender the right to be elected a member of the board, or to vote in the elections. In Prussia some years ago the Government asked the representative boards (*Aerztekammern*) if they wished to impose further penalties on delinquents. The great majority of the provincial boards declined the proposal; some, however, were willing to adopt it, provided that they were allowed to judge also the medical officers of the army and the civil service. As the Government totally refused this condition the matter dropped. The kingdom of Saxony now proposes to its medical board that a Bill shall be brought before the Saxon Parliament in order to extend the powers of the boards. According to that Bill the medical boards shall draw up a code of ethics and shall form a court of honour (*Ehrenrath*) for each district, which will judge infractions of this code. If the court, after trial, thinks a medical man guilty it may, according to the degree of his culpability, punish him by simple warning, by reprimand, or by a fine of from 20 to 1500 marks (£1 to £75). The defendant shall have the right of appeal to a superior court consisting of a learned judge and three members of the profession. The decisions of those medical courts shall have the same authority as if pronounced by an ordinary law court. The medical assessors, however, should not be subject to the jurisdiction of the board. This proposal of the Saxon Government is of the utmost importance. Medical men have not hitherto been authorised to impose penalties on their professional brethren for ethical misdemeanours. If the Bill becomes law—which, however, is still very doubtful—a great responsibility will be laid on the medical judges. The success, if any, of the experiment contemplated by the Saxon Government will unquestionably depend upon the good sense and the tact of the members of the courts. If it proves successful, other German Governments will probably follow the example of Saxony. Many medical men, however, doubt whether the ethical tone of the profession will be improved by the legal enactment of a code and the infliction of penalties.

ROME.

(FROM OUR OWN CORRESPONDENT.)

he Red Cross in Abyssinia.

THE mountain ambulance, consisting of fifty beds, sent by the Croce Rossa Italiana to Abyssinia, arrived at Massowah on the 28th ult., having had a successful transit, and a hearty welcome at every stage—Naples, Messina, and Alexandria—at which it touched. Its immediate destination is the upland of Asmara, the summer quarters of the army of occupation. The health of the entire *personnel* leaves nothing to be desired, and the most cordial relations are already established with the combatant force, the superior officers of which have arranged that the medico-surgical staff of the Red Cross shall regularly share their mess. Dr. Gino del Prete, the head of the mountain ambulance, writes in the most gratified terms of the success, so far, of this new experiment in African warfare—a success which has had a healthy stimulative effect on all the subcommittees and female sections of the Red Cross Association throughout Italy. These subordinate branches of the organisation have already been of signal

service to the central committee in collecting funds for the mountain ambulance now in Abyssinia—the sub-committees, for instance, of Piacenza, Vicenza, and Bari having each subscribed 500 fr. (£20), while those of Mantua and Padua have contributed 300 fr. each, and others in like proportion according to their ability. The subcommittee of Padua, besides its subscription of 300 fr., has undertaken to provide, at its own expense, the entire outlay of the mountain ambulance in the department of *matériel*, and that of Verona has volunteered to supply it with liqueur cognac and 2000 of the finest lemons from the famous groves on the Lago di Garda.

The Earthquake in Florence.

Not for centuries has the City of Flowers—or, for that matter, Tuscany—sustained so severe a shock of earthquakes as at 8.55 on Saturday evening, May 18th. In the neighbourhood of Florence the casualties were much greater than within the gates. At Lampeggi, for instance, there were at least three deaths from the collapse of outhouses belonging to the famous Medici Villa, which itself was damaged beyond all recognition. The skilled seismologists at the two observatories—that of the Querce and that of the Scolopi—were unable to predict the catastrophe in time, although the Padre Bertelli at the former, by the tromometer he invented in 1870, was able to give more than an hour's notice of the earthquake of 1873—the last considerable one experienced in Florence. All the indicators were, however, at fault on this occasion, the earthquake being characterised by movements rarely found in combination, and assuming, as the Padre Giovannozzi of the Scolopi has announced, a movement “*ondulatorio, sussultorio e vorticoso*” (undulating, subsultory, and eddying) all at once. Besides the absence of fatal cases Florence may congratulate herself on being spared any considerable damage to her works of art or her world-famous buildings. The alarm caused to the inhabitants, however, was great, and half the population bivouacked in the streets or patrolled the city all night in carriages or humbler vehicles. In conversation with a distinguished alienist this morning I was told that within the last decade, and more notably since the terrible cataclysms in the island of Ischia in 1881 and 1883, to say nothing of the now almost epidemic convulsions of the earth's crust in southern Italy, a distinct fear peculiar to the inhabitants of earthquake-haunted districts has manifested itself often enough to entitle it to a subsection under *pantophobia*—“*seismophobia*” being the term proposed in classification. Of course, a certain neurosis, most marked in super-sensitive, ecstatic, abnormally emotional natures, must underlie the particular development of derangement, but the subject still awaits systematic study and discussion. Meanwhile the scenes at the Florentine hospitals during and after the shock of Saturday evening were as instructive as they were painful. In the Santa Maria Nuova the patients, with few exceptions, even those suffering from grave maladies, leaped out of bed, all of them making for the doors. The physicians and their subordinates tried in vain to induce calm—the patients would insist on going out at any cost. Curiously enough the inmates of the “*Corsie Veneree*” (syphilitic wards) were the most panic-stricken, the whole of them leaving the hospital *en masse* only to return, however, next morning. At San Giovanni di Dio and the Maternità di San Salvi similar scenes were witnessed. Science awaits further developments of seismology, not only in the greater refinement of its instruments, but also in the direction of the late Padre Denza's¹ researches, which have gone far to determine the probable trend of the “*seismic axis*” in earthquake visited regions and have laid something more than the foundation of a working theory of telluric storms.

The General Election.

“Eclipse first and the rest nowhere,” describes Dr. Baccelli's triumph at the poll in the third electoral division of Rome on Sunday last—indeed, his Excellency was not seriously opposed. The returns already known in the various cities and provinces give a clear majority for Signor Crispi—a majority which cannot possibly be much affected by the supplementary ballotings on Sunday next, and which, it is to be hoped, will continue strong enough to admit of his entering on the statute-book the various reforms, educational and administrative, for which Italy has long been yearning. Among these Dr. Baccelli's University Bill has a prominent place, and if carried into law without organic modification will mark an era in professional qualification, especially in the faculties of medicine and law.

(FROM OUR OWN CORRESPONDENT.)

Small pox and Vaccination.

RELIABLE statistics relating to vaccination and small-pox are not often forthcoming in this country. This renders the following figures even more valuable than they would otherwise be. The figures were collected by Dr. A. N. Sotin and published by him in a dissertation to the St. Petersburg Academy last year. He was led to collect the statistics in the following manner. The *volost*, or subdistrict, of which he was in charge lay in the western corner of the Mologn *uyezd* or district, in the government of Yaroslavl. Observing that an epidemic of small-pox was approaching from the east, Dr. Sotin personally examined every child under fourteen years of age in his district before the disease arrived. The total number of children examined was 1564, distributed amongst 665 families, and in thirty villages. He found that 1055 had been vaccinated and had visible scars; 75 children formed a second group of doubtful cases, which were said to have been vaccinated, but in which no scars were visible; and 434 had never been vaccinated. The small-pox arrived and a wide-spread, though not very fatal, epidemic resulted. It was then found that of the 1055 "vaccinated" children only 16, or 1.3 per cent., had contracted the disease; of the 75 "doubtful," 35, or 46.6 per cent., suffered; while of the 434 "unvaccinated" children as many as 244, or 56.2 per cent., caught the disease. In other words, the unvaccinated suffered to an extent forty-five times as great as the vaccinated. Further, it was observed that in 189 families all the children were unvaccinated, and in these families if one child sickened with the small-pox the disease spread (with only seventeen exceptions) to every other child in the house. On the other hand, in houses where some children were vaccinated and others not, the disease always attacked the last, and the first escaped. Dr. Sotin believes that there is no danger from vaccination performed during a small-pox epidemic, but that general vaccination will with certainty cut short an epidemic, and that the immunity following vaccination does not last more than eight years, at the end of which time revaccination is necessary.

The Diphtheria Antitoxin.

At a recent meeting of the Kazan University Medical Society Professor Kazem-Bek reported 30 cases in which he had employed the antitoxin. In 17 of these cases only was Löffler's bacillus demonstrable. In all the administration of the remedy was followed by marked improvement both in the local and the general symptoms. There was only 1 death, that of a patient with severe renal complications. A scarlatiniform rash appeared in two patients. Dr. Rojanski had had good results with the new treatment in the children's clinique of the Moscow University. In all, 68 children had been treated with the serum since last September, and of these 13 died, the mortality rate being therefore 19.4 per cent. Before that date the diphtheria death-rate had always been from 46 to 48 per cent. Eight of the fatal cases had œdema of the neck and chest; before the introduction of the serum treatment 90 per cent. of such cases had always proved fatal. Dr. Rojanski had also given serum injections as a precautionary measure in about 100 pupils of the synodal choir school in which cases of diphtheria had occurred. One of these contracted diphtheria in a light form on the fifth day after injection. The remainder escaped infection.

St. Petersburg, May 11th (23rd).

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

A Martyr to Science.

DR. JAMES W. BYRON, who became well known as a bacteriologist through valuable service which he performed as a member of the quarantine staff, died in the New York Hospital on May 6th from tuberculous phthisis, aged thirty-four. He had been ill with the disease for more than a year

and his case was remarkable because he contracted the disease while he was studying the tuberculous bacilli in the Loomis Laboratory. He was the first to make the discovery that he had contracted the disease. He was in vigorous health at the time he began his studies and weighed 165 pounds. It was Dr. Byron's custom to receive samples of the sputum of persons who were suspected of having incipient phthisis and to examine them under a powerful microscope in order to detect, if possible, the presence of the bacilli. Dr. Byron said months ago, when he knew that he had contracted the disease, that he must have become careless after some of his examinations and allowed the samples of sputum to become dry. In that way he had inhaled the bacilli of tuberculosis without at the time being aware of the fact. Early last year Dr. Byron began to have a hacking cough and his suspicions were aroused. He examined his own sputum and made the discovery that he was suffering from tuberculous phthisis. He made repeated examinations and each time discovered the bacilli. He did not appear to be greatly alarmed by the discovery which he had made, but he told his friends of his condition and made no secret of the manner in which he had contracted the disease. He was advised to seek a warmer climate, and he went to Southern Italy in the hope of regaining his health. He remained abroad all the summer but he returned to the city in the fall much worse than when he went away. He had wasted almost to a skeleton and he was so weak that he could with difficulty walk about the city. His cough was incessant and his nights were restless. Dr. Byron was attacked with dangerous hæmorrhage of the lungs on May 8th, and he thought his death might occur immediately. He was removed in an ambulance to the New York Hospital, where his condition seemed to improve slightly. Another and fatal hæmorrhage occurred the next day. A citizen has contributed \$500 towards a memorial to this "martyr to science."

Tax on Medical Men.

The North Carolina Legislature, composed in part of members whose constituency depends upon the gratuitous services of physicians, has imposed an annual tax of \$10, to be paid into the state treasury for the privilege of practising medicine. "That," remarks the *North Carolina Medical Journal*, "is a damnable outrage, worthy of the gang who perpetrated it, and we feel sure that among the first things done by the next Legislature will be the repeal of this section. In the meantime, we suggest to those doctors who may have to serve one of the Solons (!) who voted for this tax, that they increase their charges to cover the amount of the tax. If the legislator be a dead-head, as he is now a dead letter, cast him off and let him go to ———! no, the country doctor."

A Memorial to Dr. Loomis.

The late Dr. Loomis inherited tuberculous phthisis and in early life had marked symptoms of that disease. He had long anticipated an attack of lung affection which would prove fatal, and it finally came in the form of a pneumonia which quickly ended his life. Hence his attention was more directed to phthisis pulmonalis than to any other disease. He had studied the effects of climates more thoroughly than any other physician in this country. It was largely through his efforts that the Adirondacks became a popular mountain resort for phthisical patients. In recent times he became interested in the highlands of Sullivan County as a health resort for those suffering from lung affections, and it has been learned since his death that he contemplated establishing a sanitarium for persons suffering from phthisis, who had limited means, in that region. A lady patient who had been benefited by a residence in these mountains has offered a large sum for the purpose of purchasing a tract of land and erecting suitable buildings for a sanitarium. Her purpose is to carry into effect Dr. Loomis's ideas. The establishment is to be called "The Loomis Sanitarium" and will be exclusively for the benefit of those suffering from phthisis who would not otherwise be able to leave the city.

A Typhoid Fever Epidemic due to Infected Milk.

The State of Connecticut is now suffering from a terrible visitation of typhoid fever, Stamford and New Milford being the places where the epidemic has raged most severely. The medical records of the State do not show an epidemic equal in extent to that at Stamford. It began three weeks ago with a score of cases in various parts of the city and spread rapidly. At first physicians were unable to explain it, but it was soon traced to the milk from a farm. The total number of cases since the disease began is 327, the deaths numbering 5.

¹ It may be as well to explain briefly the administrative divisions of the Russian country. Each village constitutes a rural commune or *mir*; a number of rural communes are united together to form a *volost*; a number of these, again, constitute an *uyezd* or district; while the largest administrative division of all, containing many *uezds*, is called a *gubernia* if under civil rule or an *oblast* if under military rule. European Russia is divided into sixty such large divisions.

All the deaths and most of the cases reported can be directly traced to the infected milk-supply. The State Board of Health issued the following bulletin. "The most severe epidemic of typhoid fever of which there is any record in Connecticut is now in progress in Stamford. Thus far more than 200 cases have occurred in the town of 18,000 inhabitants. Careful investigation of its origin is now being made, and in due time will be published. The evidence at present seems to be conclusive that the disease spread from infected milk, and that the milk became infected by washing the cans in water from a highly polluted well. How the special infection got into the well has not been definitely determined, but the close proximity of two vaults is suggestive. There could not be a more convincing illustration of the importance of some authoritative supervisor of the ways and methods of milk production for public use."

Comparative Qualifications of the Graduates of Different Schools of Practice.

The State of New York has three State examining boards, representing the "regulars," the "homœopaths," and the "eclectics." The schedule of questions is alike for each. An analysis of the results of the licensing examinations since Sept. 1st, 1891, shows that 8.9 per cent. of the "old school" candidates were rejected in 1892, 7.4 per cent. in 1893, and 20.3 per cent. in 1894; that 25 per cent. of the "homœopathic" candidates were rejected in 1892, 9.5 per cent. in 1893, and 13.7 per cent. in 1894; and that 50 per cent. of the "eclectic" candidates were rejected in 1892, 28.5 per cent. in 1893, and 50 per cent. in 1894. During the three years 56, 267, and 390 "old school" candidates have been examined; 8, 21, and 51 "homœopaths"; and 4, 7, and 4 "eclectics," making a total of 808, of which number 121, or 15 per cent., were rejected. This result is remarkable when it is considered that admission to the licensing examinations presupposes the preliminary education required by statute, and graduation with the degree of Bachelor or Doctor of Medicine from a registered medical school.

May 17th.

Obituary.

JOHN NOTTINGHAM, F.R.C.S. ENG., L.R.C.P. LOND.

THERE has lately passed away a very remarkable man who once occupied a prominent position in Liverpool, where he was known to almost everyone and highly respected. Mr. John Nottingham came from Yorkshire and was apprenticed to the father of Mr. C. G. Wheelhouse. He studied medicine and surgery at Guy's Hospital and in Paris under Dupuytren and Velpeau, and some time about the year 1837 was appointed house surgeon to the Liverpool Infirmary, as it was then called, now the Royal Infirmary. While there he was noted for the eagerness with which he pursued his clinical and pathological studies, and a contemporary friend who survives him has recounted to the writer occasions on which they made post-mortem examinations together in the early morning, a time of day when Mr. Nottingham was actively at work during a good portion of his long life. He was a great student, an omnivorous reader with a most retentive memory, and a very good linguist, the consequence being that his well-stocked brain, great conversational power, and affable manner made him a charming companion to his friends. He began general practice (without midwifery) in the centre of Liverpool about the year 1840, and quickly succeeded in getting plenty of work, especially surgical, to which he was introduced by practitioners of his own age who had less taste and capacity for surgery than himself. In a very few years, at the death of a Mr. Wainwright, who had a large practice in the then charming and wealthy suburb of Everton, Mr. Nottingham settled in the neighbourhood. Here he lived for many years, in fact until he retired from practice altogether. In conjunction with the late Mr. J. Penn Harris and other friends Mr. Nottingham founded the St. Anne's Dispensary, an institution which quickly attracted notice and popularity, and where he devoted himself to the study of ear and eye diseases. Later, the St. Anne's Dispensary became merged in the Liverpool Dispensaries, and is now known as the East Dispensary. In 1850 or so Mr. Nottingham was

appointed surgeon to the Southern Hospital, where his general surgical work was characterised by prudence, ingenuity, and considerable operative address. During his period of office, in 1872, this hospital was rebuilt on a larger scale on a new site and reopened as the Royal Southern Hospital. Soon after his retirement from hospital practice he became affected with cataract and passed a couple of years in a state of practical blindness. This affliction, which would have tried many men of equal intellectual vigour, he bore with conspicuous patience, and left Liverpool for his country retreat at Whitchurch, Salop, where he remained secluded from all but a few intimate friends until relieved by the extraction of his cataracts by Mr. Bader in 1880 and 1881 respectively. His sight became and continued useful for years, and he lived at Whitchurch for the rest of his life. At Christmas, 1887, an acute inflammation of one eye took place after slight exposure one chilly evening, and he submitted a few days later to extirpation of the globe, rapid healing and recovery ensuing. He continued always very timid about his sight, apparently from a dread of losing the second eye, and never went out unless he was thoroughly muffled and veiled. For the last twenty years he had been invalided, first by blindness, then by bronchitis, and latterly by senile decay. He was apparently merely worn out, and died on May 7th, at the age of eighty-four and a half years. He married Miss Sarah Worthington, of Whitchurch, to whose unrelenting care and attention he owed the comfort of his declining years.

HUGH THOMAS, M.R.C.S., L.S.A.

THE result of an accident on the evening of May 22nd cut off Mr. Thomas in the prime of life. It seems that he was returning home from visiting a patient when, crossing from the footpath to a tramcar, he was knocked down by a butcher's horse and cart. He did not complain much at the time, but died the following afternoon. It was found at the post-mortem examination that there was a severe laceration of the liver and that three ribs were broken. Mr. Thomas was born in 1850 and was a native of Beaumaris. He received his medical education at Queen's College, Birmingham, where he passed an exceptionally good curriculum. He became L.S.A. in 1876 and the following year M.R.C.S. For some time afterwards he was resident at the Queen's Hospital and subsequently settled in practice at Small Heath, one of the suburbs of the town. Here, amid the arduous duties of a rapidly increasing practice, he became a popular and respected citizen. Taking a great interest in municipal matters, he was returned as councillor for the Bordesley Ward in 1887, and again three years afterwards by a large majority. In politics he also took a keen part. He was ever ready to promote the well-being of the poor and to devote his energies to their relief and interests. The opportunities of his public position enabled him to advocate various reforms and to prove himself an enlightened and advanced member of the community. Mr. Thomas leaves a widow, but no children.

THOMAS BOOTH BRIERLEY, M.B., C.M. EDIN.,
M.R.C.S. ENG., L.R.C.P. LOND.

A VERY promising career has been cut short by the death, on May 14th, of Dr. Brierley, jun., of Tattenhall, Cheshire. The deceased gentleman, who was only twenty-six years of age, studied medicine in Edinburgh and at St. Thomas's Hospital and graduated at Edinburgh University in 1891. He had recently been acting as house surgeon at the Sheffield Children's Hospital and was hoping to join his father in practice at Tattenhall, when he was seized with an unexpected illness which rapidly proved fatal.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. G. Coppola, Professor of Medical Pathology in Palermo.—Dr. Fernandez de la Vega, formerly Professor of Anatomy in the University of Saragossa.—Dr. Godoy y Rico, Professor of Operative Medicine in Granada.—Dr. Maklakoff, Extraordinary Professor of Ophthalmology in the University of Moscow.—Dr. Isaac Himes, Professor of Pathology in the Western Reserve University of Cleveland.—Dr. B. F. Westbrook, Professor of Anatomy and Surgical Pathology in Long Island College Hospital, Brooklyn.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE summer sitting of the General Medical Council, which opened on Tuesday, May 28th, had before it a full and important programme. The attendance upon each day has so far been very good.

The official announcement of the resignation of Sir John Simon, though not coming to the members of the Council as new information, was received with very general regret. Sir Richard Quain's graceful allusions to the services of his late colleague were heartily endorsed by Sir William Turner, while all who know Sir John Simon will recognise that by his retirement the Council have lost a most wise voice in their deliberations, as well as a most valuable and responsible councillor in the eyes of the medical public. The appointment of Dr. Thorne Thorne to the vacancy will, we know, be thoroughly acceptable to all our readers. Sir John Simon, with the prestige arising from the scientific and practical work that he has done and the high offices that he has discharged with eminent success and dignity, must necessarily leave behind him a vacancy difficult to be filled; but in the medical officer to the Local Government Board a successor has been selected of whose merits there can be no doubt, and whose record is so well known that we need not expatiate upon it.

The President of the Council, who is also chairman of the committee engaged upon the revision of the British Pharmacopœia, not unnaturally devoted a great portion of his opening address to consideration of the direction that revision should take. His position in the matter is well indicated by his words, "it is desirable that the Pharmacopœia should not be made a book on Therapeutics and Pharmacology," and it is a position which is very tenable. All the profession have been aware that the present edition of the Pharmacopœia would be the better for emendation and perhaps for considerable omission, but it does not follow that it would become a more useful book by transforming it into a treatise on medical treatment. And certainly this is not the object of a work bearing the title "Pharmacopœia."

There seems to be an immediate prospect of structural improvement in the buildings occupied by the Council, since arrangements are being made for a more permanent tenancy of 299, Oxford-street. In accordance with a resolution passed by the Executive Committee of the Council on Feb. 25th, 1895, the President and Treasurer, with the coöperation of the solicitor and the architect, have completed the formal arrangements for the purchase of the freehold reversion of the premises, of which a portion is now in the Council's occupation. Plans of alterations in the buildings occupied by the Council are ready and will be submitted to the Council for approval—dependent of course upon the completion of the purchase.

TUESDAY, MAY 28TH.

SIR RICHARD QUAIN, President, in the chair.

Opening of the Session.

The fifty-eighth session of the General Council of Medical Education and Registration was opened at the offices of the Council, Oxford-street, London, on Tuesday, May 28th. Sir Richard Quain, President of the Council, occupied the chair, and there were few vacant places around the table. Mr. W. J. C. Miller (Clerk to the Council) officially announced the resignation of Sir John Simon, as one of the Crown repre-

sentatives, and the appointment of Dr. R. Thorne Thorne to fill the vacancy. Dr. Thorne Thorne was introduced to the President and Council by Sir Dyce Duckworth.

THE PRESIDENT'S ADDRESS.

THE PRESIDENT, in his opening sentences, referred to the loss the Council had sustained by the resignation of Sir John Simon, and paid an eloquent tribute to his labours. He then, in the name of the Council, welcomed Sir John Simon's successor, Dr. Thorne Thorne. The President continued: During the year ending Dec. 31st, 1894, 1426 medical practitioners were registered, a number which may be compared with 1579 in 1893, and 1513 in 1892. During the year 1894 1671 medical students were registered, a number which may be compared with 1747 in 1893, and by a singular coincidence with exactly the same number, 1671, in 1892. A slight falling off will be observed in all but one of these instances.

[He then passed to the consideration of the revision of the Pharmacopœia. Beginning from the earliest known Pharmacopœia issued at Nuremberg in 1542, he went on to give a *résumé* of the history of the British Pharmacopœia and its various editions, and continued:]

After an interval of ten years since the last edition of the Pharmacopœia was published it is proposed to issue a new edition. In this interval very considerable movement has taken place in all the matters which relate to the composition and construction of the Pharmacopœia. It may well be questioned whether that movement is in all instances one of progress, but, whether it is so or not, it is the duty of the Council to take care that, in all that relates to it, the work is as accurate and complete as the most diligent research, care, and experience can make it. With a view of obtaining the fullest information on the subject, communications have been addressed to the whole of the licensing authorities, inviting suggestions as to additions, omissions, and emendations, and sixteen of these bodies have responded. The reports with which they have favoured the Council show the great interest and care which they have devoted to the subject. All these reports have been printed for the use of the Pharmacopœia Committee. A request for coöperation in the work was also addressed to the Pharmaceutical Society, which has responded by sending a report on the articles which, in the opinion of its council, should be added to or omitted from the Pharmacopœia. The Council are greatly indebted to the several medical licensing authorities for the assistance which they have thus rendered. Communications have also been received from India and the colonies through official sources. These communications have also been printed for the use of the committee. The interest which the preparation of the Pharmacopœia has excited might be judged by the numerous papers which have appeared in the various journals and by communications from other sources. It will be the duty of the Pharmacopœia Committee, increased in number if thought fit by the Council, to thoroughly investigate these various communications, of which analyses and summaries have been prepared for their convenience by the editor. For this purpose it will be necessary for the committee to hold a special meeting during the summer or autumn as may be most convenient to the members, the fees for which should be as for a meeting of the Executive Committee, according to a former precedent. Perhaps I may here point out briefly the conditions under which the Pharmacopœia Committee will have to act. They will have to regard, first, the legal definition of their duties as set forth in the Medical Act; secondly, they will have to regard their duties to the profession, which will require them to decide as to those preparations which should be omitted and those which should be introduced—to repeat a quotation of the remarks of the Royal College of Physicians of London, to which I have already called your attention, by rejecting medicines of little use, altering formulæ that are absurd and inconsistent, excluding such as savour of superstition, and generally endeavouring to make the work consonant with reason and experience; they have, thirdly, to regard the interests and education of pupils who have to make themselves acquainted with the contents of the work. Above all things, it is desirable that the Pharmacopœia should not be made a book on therapeutics and pharmacology. To do this would be to introduce a great novelty into the practice of physic—that is, the treatment of disease by Act of Parliament. My conviction is that the forthcoming edition of the British Pharmacopœia will be one worthy of the Council under whose direction it is issued. The attention of the General Medical Council has been

called by the Lord President of the Council to a Bill on the subject of midwifery, which has been introduced by Lord Balfour of Burleigh and read a second time in the House of Lords. With a view of giving the members of the Council time for the consideration of this subject, I have caused to be forwarded to each a copy of the letter from the Privy Council, together with a copy of the Bill, and also copies of the last resolutions previously adopted by the Council on the like subject. In addition to this communication, the subject of the registration of women for the practice of midwifery will be brought before the Council by numerous and varied communications in regard to the question, and by a deputation from the Lancashire and Cheshire Branch of the British Medical Association. These communications have been collected in the form of a pamphlet, which will be in the hands of members.

The visitation and inspection of the Final Examinations are not yet quite complete. The examinations of the Conjoint Board in Ireland of the Royal College of Surgeons and the Apothecaries' Hall were revisited in April last by Mr. Wheelhouse, accompanied by Dr. Duffey, the inspector, and a report will be presented. The Examination Committee will present a report on the Final Examinations for further consideration. As the visitation and reports are not yet quite complete it will be necessary to postpone any immediate action on the following resolution of the Council passed on Dec. 4th, 1894: "That the Council, in pursuance of its resolution of Nov. 27th, 1891, arrange for the visitation and inspection of the several examinations in physics, chemistry, and elementary biology, held by the various licensing bodies in the years 1895 and 1896."

On Dec. 13th, 1894, the Registrar requested the licensing bodies to furnish the dates of these examinations, and, with a few exceptions, the requisite information has been supplied by them. In accordance with the resolution of the Council passed on Nov. 29th, 1894, the reports on the examinations in Public Health have been circulated amongst members prior to this meeting. In addition to those already presented at the last session, it will be noticed that there are now reports on the examinations of the Conjoint Board in England, the Conjoint Board of Physicians and Surgeons in Ireland, and the Universities of London and Dublin, all inspected by Dr. Duffey, leaving reports on the Royal University of Ireland, the Victoria University, and the Universities of Oxford and Glasgow to complete the series of reports on examinations in Public Health. The Examination Committee will also present a report on the returns from the public departments of the results of the competitive examinations for commissions in Her Majesty's Services. The Education Committee will present a report dealing with communications from the Scottish Universities Commission, from the University of Wales, and also dealing with the question of the registration of dental students. This reference to the subject of the reports by the Examination and Education Committees cannot be made without acknowledging the services of these committees, but more especially of their chairmen, Sir Dyce Duckworth and Dr. Tuke. The duties of the chairmen have involved much correspondence and much consideration before the reports could be submitted, labours which claim, and cannot fail to receive, the best thanks of the Council.

Since the last meeting of the Council twenty-one charges of alleged misconduct by registered medical practitioners have been received. All these charges have been investigated by the solicitor and the Penal Cases Committee, who decided that fifteen cases should be set aside and that six of these practitioners should be summoned, five to attend during the present session and one, residing in Australia, at the November session. In reference to dental business I may mention that Mr. Charles S. Tomes, F.R.S., the visitor to the dental examinations appointed by the Council, has commenced his visitation and will present a report on the examinations of the Faculty of Physicians and Surgeons of Glasgow. The examinations of the other dental licensing bodies will be visited during the present year. One case of a penal nature will be considered by the Dental Committee, who will find the facts and report thereon to the Council. In conclusion, I feel that I must not detain you longer from the consideration of the many serious and important matters which will now come before you.

Mr. WHEELHOUSE moved that the Council do thank the President for his address and ask his leave to have it printed and inserted in the minutes.

Sir WILLIAM TURNER, in seconding the motion, asked to be allowed to re-echo all that the President had said with regard to Sir John Simon. All members of the Council must have been strongly impressed with the thorough, masculine, statesmanlike grasp that he had of all subjects, educational and otherwise, which were brought before the Council, and he (the speaker) for one felt it as a great loss that he was no longer with them. He wished also to welcome Dr. Thorne Thorne. He felt that the Lord President of the Council, in appointing so eminent a public servant, showed his desire that this Council and the most important branch of the public service which Dr. Thorne Thorne represented should move in unison, and it was the more especially necessary that this should be now that this Council was entrusted with such large powers under the Act of 1886 in connexion with the inspection, and indeed the authorisation, of registrable diplomas in public health.

Dr. HAUGHTON expressed his interest in what had fallen from the President with reference to the Pharmacopœia, and asked the Council not to forget the great work done by the President himself in this connexion. He (Dr. Haughton) believed very much in general education—Latin, Greek, and mathematics—but he asserted that their predecessors here, in working out the British Pharmacopœia, did a work which they would find it very hard to rival, much less to surpass.

The PRESIDENT assured Dr. Haughton that his work in connexion with the Pharmacopœia had always been a great pleasure to him.

The motion was cordially agreed to.

PROCEEDINGS OF THE COUNCIL.

Business Committee.

The following members were appointed to the Business Committee: Mr. Wheelhouse, Sir William Turner, Mr. Bryant, and Dr. William Moore.

Yearly Tables.

Sir WILLIAM TURNER handed in a series of yearly tables as to the results of professional medical examinations, examinations for qualifications in State medicine, professional dental examinations, &c., and suggested that there should be no discussion upon them until the Council had received a report on the question of the form of the returns.

Midwives Registration Bill

Mr. MILLER read the following communication on this subject—viz.:—

"Privy Council Office, Whitehall,
"May 16th, 1895.

"SIR,—I am directed by the Lord President of the Council to transmit to you, to be laid before the General Medical Council, the enclosed copy of the Midwives Registration Bill now before the House of Lords; and I am to request that you will move the Medical Council to favour his Lordship, as early as possible, with any observations they may decide to offer in regard to the Bill.

"I am, Sir, your obedient servant,
"C. L. PEEL."

Sir WILLIAM TURNER moved: "(a) That the Midwives Registration Bill, transmitted by the Lord President of the Council, be referred to the committee of the Council appointed on Nov. 20th, 1890, to consider the provisions of any Bill for the registration of midwives which may be submitted by the Government to the Council. (b) That the two vacancies in the committee should be filled by a member from each of the Irish and Scottish Branch Councils. (c) That the committee should report to the Council as early as possible during the present sitting." The Council, he said, so far back as November, 1890, anticipated that a Bill connected with the registration of midwives would in course of time come before the Council for its consideration, and they passed a resolution to the effect "that a committee, consisting of the President, Sir John Simon, Dr. Quain, Dr. Glover, Sir Walter Foster, Mr. Carter, and Mr. Wheelhouse, be appointed to consider the provisions of any Bill for the registration of midwives which may be submitted by the Government to this Council." It would be noticed that this committee consisted entirely of members of the English Branch Council, and he saw no reason, seeing that the Council were now in session, why they should not have representatives upon the committee of Ireland and Scotland. Two of the gentlemen named in the resolution were no longer members—namely, Sir John Simon and the then President, the late Mr. Marshall. There were, therefore, two vacancies.

Dr. MACALISTER seconded the motion.

Dr. GLOVER suggested that Sir William Turner and Dr. Thorne Thorne should be appointed to the Committee. The

nationality question did not come in here because the proposed legislation did not apply to Ireland or Scotland.

Dr. HAUGHTON concurred in this suggestion. He had spent a great deal of time in reading this Bill, and he was greatly astonished by it. A more extraordinary Bill he never read in his life. He was glad, however, to find that Ireland and Scotland were to be left alone, and he advised Irish and Scotch members of the Council to have nothing to do with the Bill.

Dr. HERON WATSON reminded Dr. Haughton that it was the opinion of the General Medical Council, and not that of the English Branch Council, which the Lord President desired.

Sir WILLIAM TURNER said he understood it to be the intention of Dr. Bruce to nominate Dr. McVail, and in his absence he would do so.

The PRESIDENT thought they must insist on the aid of Sir William Turner.

Dr. McVAIL said he would have much pleasure in supporting the nomination of Sir William Turner.

Other names having been suggested, it was decided that the committee should be given general power to add to their number, and the motion thus amended was agreed to.

Sir WALTER FOSTER had on the notice paper a motion to this effect: "That this Council, while desiring to improve the education, training, and control of midwifery nurses, cannot support the 'Bill for the Registration of Midwives,' now before Parliament, inasmuch as that Bill would give a legal status to women who are not properly qualified to take sole charge of midwifery cases." Sir Walter Foster said he thought the Council had adopted a wise course in referring the Bill to this committee, and he would defer action on this motion until the report of the committee had been received.

Dr. MACALISTER pointed out to the Council that on the following day they were apparently to receive a deputation of fourteen members from the Lancashire and Cheshire Branch of the British Medical Association to speak on this Bill, among other subjects. Having regard to the reference just made to the committee, he thought it would be waste of time for the Council to hear the deputation, and suggested that it should go before the committee.

The PRESIDENT said they must receive the deputation, because they had promised to do so.

Dr. GLOVER thought it most desirable to receive the deputation. His only regret was that they were not to receive a deputation on the other side of the question.

Sir DYCE DUCKWORTH was sure the Council would be greatly maligned if they did not receive the deputation.

Sir WALTER FOSTER said that any attempt to prevent the deputation coming before the Council would be viewed not only as an act of discourtesy, but would be more or less unconstitutional in its character.

Dr. HERON WATSON thought the Council could make no greater technical error than to refuse to receive this deputation.

The matter was not pressed further, members understanding that the deputation would be received.

PHARMACOPEIA COMMITTEE.

Dr. LEECH moved: "That standing order No. 8 be amended as follows: 'The Pharmacopœia Committee shall consist of the President of the Council and eight members, of whom four shall be elected from the English, two from the Scotch, and two from the Irish Branch Council. The Pharmacopœia Committee shall have charge of all matters relating to the preparation and publication of the Pharmacopœia, and shall report from time to time to the General Medical Council.'" It was pointed out last session that the committee was not quite according to the standing orders, and that in consequence the committee might be placed at a disadvantage in its work. He thought it very desirable that each of the divisions of the kingdom should be represented on the committee.

The motion was agreed to, and the following members were nominated to the Committee: The President, Sir Dyce Duckworth, Mr. Carter, Dr. MacAlister, Dr. Leech, Dr. Batty Take, Dr. McVail, Dr. Charles Moore, and Dr. Atthill.

The Society of Apothecaries.

On the motion of Mr. CARTER, it was agreed to appoint Mr. Bilton Pollard an Assistant Examiner to the Society of Apothecaries, in place of Mr. Andrew Clark, who retires by rotation.

The Council then adjourned.

WEDNESDAY, MAY 29TH.

The Council resumed to-day, Sir Richard Quain in the chair.

The Midwives Question.

The first business of the Council was to receive a deputation from the Lancashire and Cheshire Branch of the British Medical Association on the following questions: (1) the diplomas issued by the Obstetrical Society and other bodies; (2) the continuance of lectures by unauthorised persons on midwifery to persons other than registered students of medicine; and (3) the Midwives Bill at present before Parliament. The deputation consisted of James Taylor, F.R.C.S. Eng., ex-President Lancashire and Cheshire Branch British Medical Association, senior surgeon to the Chester General Infirmary; George Edw. Shuttleworth, B.A., M.D., ex-resident medical superintendent of the Royal Albert Asylum, Lancaster, ex-President of the Lancashire and Cheshire Branch of the British Medical Association; Sam Woodcock, M.D., J.P., President of the Medico-Ethical Association, Manchester, member of the Parliamentary Bills Committee Lancashire and Cheshire Branch of the British Medical Association; J. Brassey Brierley, M.D. Edin., Vice-President of the Medico-Ethical Association, Manchester; F. H. Walmsley, M.R.C.S., L.S.A., J.P., ex-Mayor of Salford, ex-President of the Manchester Clinical Society, Governor Owens College; W. H. Hughes, M.R.C.S., L.S.A., J.P., M.O.H., Hon. Surgeon to the Ashton-under-Lyne Infirmary, Chairman of the Lancashire and Cheshire Branch Committee of the British Medical Association; John Holden, M.R.C.S., L.R.C.P. Edin., J.P., ex-Mayor of Preston, hon. surgeon to the Preston Royal Infirmary, &c.; J. G. Gledhill, M.B. Glasg., barrister-at-law of the Honourable Society of the Middle Temple; Colin Campbell, M.R.C.S., L.R.C.P. Irel., and L.M., hon. secretary of the Lancashire and Cheshire Branch Committee of the British Medical Association; T. A. Helme, M.D., C.M. Edin., F.R.S. Edin., M.R.C.P. Lond., M.R.C.S. Eng., ex-resident obstetrician at St. Mary's Hospital, Manchester, hon. assistant surgeon to the Clinical Hospital for Women and Children, Manchester; George H. Broadbent, M.R.C.S., L.R.C.P., member of the Lancashire and Cheshire Branch Committee of the British Medical Association.

Dr. GLOVER introduced the deputation to the Council, explaining that they represented one side only of this important question, and saying he was sure they appreciated the kindness of the Council in receiving them.

The PRESIDENT welcomed the deputation. The Council, he said, were prepared to listen to what they had to say, but they had agreed not to address questions to members of the deputation.

Mr. COLIN CAMPBELL said he understood that the position of the deputation as representing the Lancashire and Cheshire Branch had been questioned, and he would be glad to know whether the Council desired him to address himself to that point.

The PRESIDENT said that was a matter for the deputation to decide.

Mr. CAMPBELL then addressed the Council. They appeared, he said, as representing the Lancashire and Cheshire Branch of the British Medical Association, and they asked the Council, as they set forth in their petition, that they would continue to object and withhold their sanction from any form of certificate or diploma issued to so-called midwives other than such as testified to the ability of the holder to act as a midwifery nurse; to declare infamous in a professional respect the conduct of those registered medical practitioners who continued to deliver unauthorised lectures on the science and art of midwifery to other than registered students of medicine; to countenance only such courses of lectures and instruction as were limited in their scope to the knowledge necessary to competence to perform the duties of a midwifery nurse; and to oppose in such a way as the Council might determine the passing of the Bill on this subject now before Parliament. All the deputation asked on the first point was that the Council should maintain the strong ground they had already taken up. They called the attention of the Council to the fact that the training of the so-called midwives and the issue of diplomas, in spite of the condemnation of the Council, still went on. In the Manchester papers, side by side with the advertisements of quacks and all sorts of specialists, there were the advertisements of lectures upon midwifery.

Dr. HELME next addressed the Council. He dwelt upon two

points—namely, the field of practice in which the midwife was called upon to work and the present system of training midwives. In Manchester, he said, Dr. Tatham had shown that of the registered stillbirths in that city 45 per cent. had been attended by women, and it was his (Dr. Helme's) settled opinion that every one of these labours must be considered abnormal. The available statistics, however, gave no idea of the real mortality, because still-born children need not be buried in a public burying ground and they could be buried without a certificate. If the midwife was to undertake to attend even so-called normal labour upon her own responsibility and without medical supervision, she must be competent to recognise concurrent disease, to diagnose abnormalities, and to deal with emergencies, and for these she required a thorough knowledge of midwifery. As to his second point, Dr. Helme read extracts from a course of lectures for midwives delivered in Manchester. As to the practical training, he said it was limited and insufficient. For three years he had had practically the sole control of a large obstetric department where 3000 labours occurred annually, and he had a good deal to do with the midwives who presented themselves for examination. Some were educated women and some were good and conscientious, but the majority were ignorant women and utterly unfit for the work of midwives. Diplomas were granted to women who had only the minimum training required—i.e., attendance on twenty labours. He would give a short experience of the training at one institution. A woman of little or no knowledge, and probably possessing little capacity for receiving knowledge, went to the house of a midwife and lived with her for from ten to fourteen days. This midwife would probably attend from three to six labours in the day, and she took this midwife pupil with her. The house was generally some miserable hovel where there was no means even of washing the patient. He himself had seen the patients lying on straw. The midwife pupil was taken to this room and saw the process of labour going on. In many cases she had not the opportunity and was not allowed to examine the case. What she did was to watch the proceedings of the woman who was almost as ignorant as herself, and after she had seen twenty of these labours she received a certificate to that effect from the midwife. This was presented to the hospital authorities and received as evidence of practical training. The woman had never seen the inside of a hospital ward and knew nothing about antiseptics. With this certificate in her possession she passed an examination of a ridiculously low standard and got her diploma, which she duly placed in her window to attract customers. She went about the neighbourhood telling people that she had got this diploma, and was consequently a very superior person. As a matter of fact she was really more dangerous than the ordinary midwife, because she raised a false feeling of security among the public. He was all in favour of high education for women, but he did not believe that the education given at present produced a woman even slightly better than the old-fashioned woman in the great majority of cases. He submitted that such a course of lectures and instruction as was now given to pupil midwives was a source of menace to the safety of pregnant and lying-in women, of grave moral danger to the public, and of great temptation to the midwife to exceed her legitimate functions.

Dr. WOODCOCK also addressed the Council. He told the Council that the Lancashire and Cheshire Branch, which was one of the largest branches of the British Medical Association, had been greatly exercised about this question of the registration of midwives. From time to time they had discussed it, and so strongly were they impressed with the necessity of some pronouncement being made on their behalf that an influential committee was appointed some time ago actively to oppose legislation such as that proposed in this Bill. A sum of £250 was voted from their reserve fund to enable them to meet whatever difficulties might be met with in the course of their legitimate work. The branch were actuated by no mere selfish motives. They knew perfectly well that a Bill such as that now before the House of Lords could in no sense safeguard the interests of the community, while it certainly stamped with the hall-mark of efficiency, on the part of the Government, women who were entirely unworthy of the position. They objected to the term midwife because it was taken by the public to mean that a midwife was a woman who was competent to undertake the entire charge of obstetric practice. The Bill emphasised this point by saying in the second clause that the term "midwife" meant a woman who undertook to attend cases of

natural labour without the direct supervision of a medical practitioner. The whole scheme of the Bill seemed to be to create an inferior order of practitioners who were to be placed on the same platform as men who had been carefully instructed in the three branches: medicine, surgery, and midwifery. They were anxious to forward a movement for the registration of all nurses. As medical men they knew the value of the assistance of educated medical nurses, and surgical nurses, and midwifery nurses. But these nurses were drawn from a very different class to the midwives. It was stated in the Bill that these women were not to be allowed to grant certificates of death or stillbirth, but there was no penal clause added, and they knew perfectly well that at the present moment midwives did grant these certificates. Dr. Woodcock then referred to the constitution, proposed in the Bill, for the Midwives' Board and condemned it in several particulars. He also took exception to the idea that medical officers of health, especially in large cities, could be expected to exercise any efficient control over midwives. In conclusion, he thanked the Council for the courtesy and patience with which they had listened to the views of the deputation, and expressed the hope that they would be favourably entertained.

The deputation thereupon withdrew.

The Council and the Scottish Universities Commissioners.

Dr. BATTY TUKE, on behalf of the Education Committee, presented and moved the adoption of a report with reference to communications which have been passing between the Council and the Scottish Universities Commissioners as to the medical curriculum. The following passages occur in the report:—

Section X. of the Ordinance of the Scottish Commissioners provides that instruction in the three subjects before passing a preliminary examination (i.e., before registration) may count as the first year of medical study. Thus the name of any Scottish university student who is permitted to avail himself of the provisions of the section may stand on the Students' Register for four years only before graduation, instead of five. This, in the words of the Commissioners, constitutes a "power of exemption conceded to the universities" which cannot be extended to the licentiates of other examining bodies. The position of the Scottish universities is therefore entirely anomalous. It has been brought about by want of consideration on the part of the Commissioners for the administrative functions of the Council, which is appointed by statute to "regulate the qualifications of practitioners in medicine and surgery." Had the Commissioners afforded to the Council the same opportunity for criticism as was accorded to the various licensing bodies in Scotland, the complication would not have arisen. Draft ordinances were forwarded to the latter, with requests that objections to any provision might be intimated. The Council was not consulted in any one particular, nor was any draft ordinance ever forwarded to its President. The consequence of this omission has been the enactment of an ordinance which is opposed to one of the most important of the Council's *Requirements*, and which directly and indirectly has seriously interfered with its action in respect of regulating medical education. The Commissioners state that they have now no power to repeal or suspend the action of this section. Judging from the concluding paragraph of their letter they appear, however, to appreciate the fact that Section X may have a detrimental effect on medical education; and they propose that, in order to facilitate its repeal after the cessation of their powers, it shall be stated in their report that their reason for declining to reconsider the propriety of the section in question is that they are powerless to record what has received Her Majesty's approval. In the opinion of the Committee, the Council must now await the expiry of the Commission, and then take steps to represent the state of matters to the University Courts of the Scottish universities. These bodies will no doubt be prepared to exercise, in respect of this section, the powers of alteration and revocation of ordinances, with the approval of Her Majesty in Council, conferred on them by Section 21 (2) of the Universities (Scotland) Act, 1889. The universities will thus be enabled to bring their regulations into accord with those of all the other licensing bodies of Great Britain and Ireland which have accepted loyally the five years' curriculum prescribed by the General Medical Council.

Sir DYCE DUCKWORTH reminded the Council that they had the remedy in their own hands of refusing to recognise the qualifications.

The report was adopted.

The Registration of Dental Students.

On the recommendation of the Education Committee, it was decided to amend the resolution on this subject so as to read: "The registration of dental students shall be carried on at the General Council office in London in the same manner as the existing registration of medical students—as hereinbefore set forth—and subject to the same regulations as regards preliminary examinations, but in the case of dental students professional study may commence by pupilage with a registered dental practitioner."

Matriculation Examination of the University of Wales.

The Council agreed, on the recommendation of the Education Committee, that this examination be accepted and that

the University of Wales be included under Division I. in the "List of Examining Bodies whose Examinations in General Education are recognised by the Medical Council as qualifying for Registration as Medical or Dental Student," on the condition that the certificate of its Matriculation Examination shall show that the student has been approved in one of the optional subjects required by the Council, and that the whole examination has been passed at the same time.

The Certificates of the Obstetrical Society of London.

Mr. MILLER (Clerk) read the following communication from the Obstetrical Society of London—viz. :—

"42, Upper Brook-street, W., May 28th, 1895.

"DEAR MR. PRESIDENT,—I beg to acknowledge the receipt of your communication forwarding to me a copy of the resolution of the Executive Committee of the General Medical Council, approving of a form of certificate for adoption by the Obstetrical Society of London.

"In reply, I beg to say that now, knowing what the wishes of the Medical Council are, I, in the name of the Council of the Obstetrical Society, accept the form of certificate approved by the Executive Committee, which shall in future be issued.

"F. H. CHAMPEYNS, President of the Obstetrical Society.

"To the President of the General Medical Council."

Mr. WHEELHOUSE, seconded by Sir WALTER FOSTER, moved that the communication be received and entered upon the minutes.

The PRESIDENT said he was sure this would be regarded as a very gratifying result of what had been an unpleasant controversy.

Dr. HAUGHTON pointed out that the form of the certificate had not been approved by the Council, but only by the Executive Committee.

Dr. HERON WATSON said the matter had been handed over to the Executive Committee.

The PRESIDENT said that in the absence of the Council it was represented by the Executive Committee in all things, even to the extent of spending £18,000 on the purchase of the site of their buildings.

Sir WALTER FOSTER warned the Council that this matter was sure to come up again, because there was a good deal of dissatisfaction about the certificate.

Sir WILLIAM TURNER said that the only point which came before the Committee was really whether this certificate issued by the Society was a colourable imitation, and in the judgment of the Committee the Society had removed from the certificate anything which would lead anybody to regard it as a colourable imitation. The certificate referred to nothing but midwifery, and it expressly said that it conferred no legal qualification to practise under the Medical Acts. It was a simple certificate that A. B. had passed an examination in midwifery.

Sir WALTER FOSTER thought the words should be added, "an examination in midwifery instituted for midwifery nurses."

Dr. McVAIL supported Sir Walter Foster, saying that if the Society objected to these words then it would be plain that they intended the certificate to be used for the practice of midwifery. He moved that the matter be referred back to the Executive Committee with a view of having such words added.

Dr. PETTIGREW thought the Council were indebted to Sir Walter Foster for the suggestion he had made.

Mr. BRUDENELL CARTER asked whether the new diploma would have the appearance of the old one. The exact wording of such a document was less important than its size and the style in which it was engraved.

The PRESIDENT said the Council had no control over the Obstetrical Society or any other society unless they did something illegal. The Obstetrical Society in the present instance had adopted the form of certificate approved by the Executive Committee, and they as a Council had really no control over the matter.

Dr. GLOVER was of opinion that this discussion was objectionable. It had for a while been irregular because no motion was before the Council. Then the subject involved was under the special consideration of a committee, and if the question was to be raised again it should not be raised until the report of the committee was before the Council.

Dr. ATTHILL thought the action of the Executive Committee had been judicious, although the form of the certificate was not what he should like to see. He approved of the suggestion of Sir Walter Foster, and thought the subject should drop.

Dr. HERON WATSON pointed out that when this matter was before the Council in December last they found that the certificate of the Society as then before them was such that it might be regarded as a docu-

ment coming within the purview of the Council's previous resolution, that certain documents issued by various societies as diplomas of education and examination were colourable imitations of diplomas conferring a legal right to admission to the Medical Register, and both contravened the spirit of the Medical Acts and were calculated to deceive the public. On receiving a communication to that effect the Obstetrical Society had held a meeting at which the matter was brought up as a matter of urgency, with the result that they agreed to submit for the Council's consideration the existing diploma and a modification of it which they hoped would meet the requirements of the Medical Council. In the same month the Executive of this Council gave the matter consideration, and came to the following conclusion: That the Executive Committee are of opinion that the words in the diploma, "a skilled midwife, competent to attend natural labour," are open to legal objection, seeing that under the Medical Act (1886) midwifery is one of the three branches in which a regular practitioner must pass an examination in order to obtain a registrable qualification. The above cited words suggest that the holder has a registrable qualification. This both contravenes the spirit of the Medical Act of 1886 and is calculated to deceive the public. Again, the formal character of the document, which is described on its face as a diploma, is fitted to deceive the more ignorant part of the public—that part which most needs protection. That the Executive Committee request the President and Council of the Obstetrical Society of London to inform the General Medical Council within one month what steps they have taken to bring their certificate within the terms of the resolution of the Council. That simply meant that the Executive Committee disapproved of the modified form agreed upon by the Obstetrical Society in February. Afterwards there was a further communication from the society begging to be informed what sort of certificate would be regarded as satisfactory in the eyes of the Council, and it was then decided by the Executive Committee that such a form as that which had appeared in the programme of business for the previous day would be satisfactory, and in his opinion it would be captious criticism to require any further change.

Dr. McVAIL formally moved: "Remit back to the Executive Committee the matter of the midwifery certificate proposed to be given by the Obstetrical Society in order that the committee may ensure that the certificate shall clearly bear out that the examination is only to ascertain the qualification of candidates for midwifery nursing."

Dr. BRUCE seconded this proposal. He contended that the Executive Committee had no power to deal with anything that was never delegated to them.

Sir W. TURNER, as a member of the Executive Committee, wished to say that this had been a matter of extremely delicate and difficult negotiations, and the Council owed a great deal to their President for the care and judgment he had shown in the conduct of these negotiations. The Executive Committee, he thought, had come to an equitable decision, and he should be extremely sorry to think that that decision was going to be questioned and fresh negotiations entered upon. The real question the Executive Committee had before them was whether the certificate of the Obstetrical Society was or was not a colourable imitation of a legal document—was a diploma in the sense of the Medical Acts, and calculated to deceive the public. When they had the draft certificates before them they took a deal of trouble to exclude anything from what they might offer to the society as satisfactory which even the most critical could say amounted to colourable imitation of the legal document, and the result was that the certificate the committee approved of was simply a certificate that A.B. had passed to the satisfaction of the signatories an examination in midwifery. That was all. The Obstetrical Society, he thought, had met them in an extremely kindly spirit, and he did not think they should disturb the arrangement come to, which seemed to him to be a very equitable one.

After some remarks by Dr. MACALISTER,

Dr. McVAIL said that if the Council settled this matter now the essential point which was referred to the Committee on Tuesday, which the Lord President had referred to this Council, and which would come up for discussion on the report of the Committee, would be practically settled, for what the Council would do, if it approved of the action of the Executive Committee, would be to approve of a certificate intended to allow a certain class of persons to practise midwifery without the supervision of this Council.

The PRESIDENT said it would now be his duty to put Dr. McVail's motion to the vote. If the subject was opened up again it must pass out of his hands, for he would have nothing further to do with it.

On the roll being called 7 voted for Dr. McVail's motion and 20 against it.

The Council's Offices.

The PRESIDENT submitted a communication on the subject of the purchase of the premises now occupied by the Council at 299, Oxford-street, and 16, Hanover-square, and on the motion of Sir William Turner, seconded by Dr. Bruce, it was unanimously resolved to accept the offer of the English Branch Council to lend £20,000 at 3 per cent. interest to enable the Council to complete the purchase. It was further resolved that the President and Treasurer have authority to complete the purchase, power being given them to purchase if necessary the interim lease of the premises. The President having remarked that it would be a very happy thing for them to feel that they were in their own freehold premises, the Council, on the motion of Dr. GLOVER, seconded by Dr. PETTIGREW, resolved to record in the minutes a vote of thanks to the President and the Treasurer for the trouble they had taken in bringing the negotiations to a satisfactory conclusion.

Members' Travelling Expenses.

On the motion of Mr. WHEELHOUSE it was agreed to receive and enter on the minutes the following reports from the Branch Councils in regard to the alterations suggested by the Executive Committee in the Standing Orders as to the fees paid to members of the Council for attendance:—

(a) From the English Branch Council.—The English Branch Council reports that it approves of the suggested alterations in the Standing Orders in the following amended shape: that Clause 4 remain unaltered, and that Clause 6 be as follows:—

	£	s.	d.		£	s.	d.
Edinburgh	6	6	0	Cambridge	1	1	0
Glasgow	6	6	0	Leeds	3	3	0
St. Andrew's	7	7	0	Manchester	3	3	0
Aberdeen	7	7	0	Birmingham	2	2	0
Dingwall	8	8	0	Newcastle	4	4	0
Dublin	6	6	0	Filey	4	4	0

(b) From the Scottish Branch Council.—The Scottish Branch Council reports that it recommends: "That the General Medical Council do adhere to Clauses 4 and 6 of Chapter XI. of the existing Standing Orders."

(c) From the Irish Branch Council.—The Irish Branch Council reports that it is of opinion: "(1) That the sum of 5 guineas is insufficient to cover the travelling expenses of the Irish members of the Council; (2) that the travelling fees of the members of the Medical Council should not be reduced, seeing that the average income of the General Council exceeds its average expenditure by a large amount."

Dr. PETTIGREW objected to any change in the standing orders. Both the Scottish and the Irish branch councils were agreed that there should be none. If the alteration suggested by the English branch council were put in operation it would press unnecessarily on the Irish as well as Scotch members of the Council.

Sir WALTER FOSTER remarked that the subject had been started because it had seemed to some of them that gentlemen from Scotland and Ireland were extremely tender in their consciences about taking too much from the funds of the Council.

The Rev. Dr. HAUGHTON wished to distinguish between Irishmen and Scotchmen. The latter had long railway journeys to take in order to attend the meetings of the Council, but they had not to cross the Irish Sea like the members from Ireland, who ought to get an extra guinea for the sea-sickness they suffered on every journey between Kingstown and Holyhead.

On the motion of Dr. WILLIAM MOORE, seconded by Dr. PETTIGREW, the recommendation of the Scottish Branch Council was accepted.

Hours of Meeting.

Sir PHILIP SMYLY moved: "That the Council shall meet each day at 11 A.M. and rise at 1.30 P.M. for lunch, and again meet at 2 P.M., not sitting after 6 P.M." In supporting this proposal he mentioned that all the members received the same honorarium; but while those resident in London had to give only three or four hours daily to the business of the Council, the Scotch and Irish members had to give day and night. By the present arrangement they were deprived of the afternoon—the interesting and amusing

time in London. They might have a portion of some afternoons if they adopted his motion. Under present arrangements the Council's sessions lasted sometimes as many as ten days. If they adopted his motion they might get through the session in five days, and that would mean a very important saving to the funds of the Council.

Dr. BATTY TUKE, in seconding the motion, said that long ago he, with Dr. Leishman, had advocated the adoption by the Council of a policy of economy and retrenchment. Both of them held that it would be far better for the members of the Council to work without any fee whatever, but they found that any such policy as theirs was not likely to be adopted by the Council, and they came to the conclusion that if the members were not to work for nothing they might be induced to work longer hours. If they would now adopt the motion before them it would tend to reduce their sessions by at least one-third, and, of course, there would be a corresponding reduction of the expense. Many of them suffered materially by being so long away from their practices, and to him personally it had on more than one occasion been a serious loss to have to stay away so long from Edinburgh.

The PRESIDENT thought it would be a great pity to disturb the arrangements which had been in existence for so many years.

Dr. ATTHILL said it was a hardship and a serious loss to the provincial members when they had to stay in London over Sunday. To get rid of the necessity for that the Council might somewhat extend the duration of the daily sittings.

Sir JOHN BANKS objected to any change.

The Council divided and rejected the motion by seventeen votes to eight.

The Medical Acts.

The Council entered on the minutes the following report: "That with regard to the communication from the Parliamentary Bills Committee of the British Medical Association (see *Minutes* for May 22nd, 1894, Vol. XXXI., pp. 45-52)—on which the Executive Committee reported on Nov. 28th, 1894, but which was recommended by the Council on the same day to the Executive Committee for further consideration and report,—the Executive Committee recommend that the Council should intimate to the Parliamentary Bills Committee of the British Medical Association their readiness to consider the provisions of any bill for amending the Medical Act (1858) or any subsequent Acts which may be submitted to this Council by the Government."

Sir WILLIAM TURNER moved the adoption of the recommendation.

Mr. WHEELHOUSE seconded.

Dr. MACALISTER asked whether the recommendation meant that the Council were ready to consider the provisions of any Bill proposed by the Government only.

Sir WILLIAM TURNER replied in the affirmative.

The recommendation was unanimously adopted.

Committees.

The Education Committee and the Examination Committee were re-elected without alteration. The Students' Registration Committee was also nominated, Dr. Hector Cameron taking the place of Dr. Bruce.

For the rest of the afternoon the Council sat in private.

THURSDAY, MAY 30TH.

The Council resumed its work to-day, with Sir RICHARD QUAIN again in the chair, and proceeded to the consideration of disciplinary cases.

Medical News.

THE annual dinner of the West London Medico-Chirurgical Society was held at the Café Royal on May 22nd. The President, Dr. Banning, was in the chair, and among the numerous guests was the President of the Royal College of Surgeons of England. Prosperity to the society was proposed by Mr. Keetley in a humorous speech, and the health of the guests was given by Mr. A. G. Wells. Mr. Christopher Heath, in replying for the visitors, mentioned that he was specially interested in this society, since he had been surgeon to the West London Hospital thirty-five years ago. Mr. Edwards proposed the health of the President, which was received with acclamation, and the evening concluded

with the toast of "The Officers," proposed by Dr. Alderson, to which Messrs. Lake and Bidwell replied. The dinner was enlivened by selections of music by the Oliveira quartet.

SUPERANNUATION ALLOWANCE.—Mr. C. H. Buncombe, F.R.C.S., medical superintendent of the City of London Infirmary, Bow-road, has been granted a superannuation allowance of £517 8s. per annum.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—

The following gentlemen having passed the necessary examination have been admitted Fellows of the College: Mr. Robert H. Cox, Mr. Sinclair Finlay, Mr. William J. Greer, and Mr. William J. Trewbella.

PRESENTATIONS.—Dr. F. Sidney Gramshaw of Stillington, Yorks, has been presented with a morocco case, suitably inscribed, containing a set of solid silver Queen Anne salt-cellars. The presentation was made by Miss Fairfax-Cholmeley (the honorary secretary), and a deputation on behalf of the ambulance classes lately conducted by him at Brandsby under the auspices of the St. John Ambulance Association.—Mr. Peter Bradford, L.R.C.P. Lond., M.R.C.S. Eng., on his resignation as resident medical officer of the Convalescent Hospital at Southport, was presented on the 16th ult., by the Chairman of the institution on behalf of the committee, with a handsome clock, inscribed as follows: "Presented to P. Bradford, L.R.C.P., M.R.C.S., L.S.A. Lond., by the committee of the Southport Convalescent Hospital as a grateful expression of their regard for his valuable services as resident medical officer for the last seventeen years."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Factory and Workshops Bill.

This Bill is still in the hands of the Grand Committee. At the meeting on Tuesday, May 28th, an attempt was made to alter the clause with reference to overtime in special trades, such as dress-making, millinery, artificial flower making, bookbinding, dyeing and bleaching, lithographic printing, &c. The clause prohibits overtime in these trades in the case of young persons between fourteen and eighteen years of age. Mr. Matthews moved to carry the prohibition only so far as to young persons under sixteen years. There was a very long debate on the question, the result being to keep the fourteen to eighteen years prohibition.

HOUSE OF COMMONS.

THURSDAY, MAY 23RD.

The Hours of Bakers.

Mr. John Burns at the commencement of this sitting presented a petition signed by 6000 operative bakers in London and the provinces, praying that the Government might see their way to reduce their working hours to forty-eight per week, having regard to the lengthy hours and the insanitary conditions in which they had to work, too frequently in underground bakehouses.

Opium and Bang in Ceylon.

Mr. Sydney Buxton, replying to Mr. Caine, said that reports had been received from the Governor of Ceylon regarding the consumption of opium and bang in the colony, but before deciding what action, if any, should be taken on those reports the Secretary of State had been awaiting the issue of the reports of the Royal Commission on Opium and of the Indian Hemp Drugs Commission. Those two reports having now been received, the Secretary of State hoped to address the Governor of Ceylon very shortly on the subject, and the correspondence as soon as it was complete would be presented to Parliament.

FRIDAY, MAY 24TH.

The Case of Dr. Cornelius Herz.

Mr. Asquith, replying to a question on this case put by Mr. Griffith Boscawen, said that the "arrest" of Dr. Herz had consisted in the presence of a police-constable in the same hotel in which he was lying ill. As it was represented to him that the fact of the officer being in the house was mentally disquieting to Dr. Herz, he recently took the responsibility of removing him. He strongly deprecated the use of such phrases as that the Government were "trifling with the life of Dr. Herz." The French Government had demanded his extradition on very serious charges, and, in reply to the suggestion of Her Majesty's Government that in view of his state of health they might withdraw their demand, they had, acting within their right, refused to do so. Under these circumstances our course was prescribed by our treaty obligations, and those obligations had been and were being performed with the greatest consideration possible for the health of Dr. Herz.—Mr. Hanbury asked whether the Government had a Bill to deal with this particular case.—Mr. Asquith replied that the Bill was one to amend the general law, but no doubt it was suggested by the circumstances of this case. The Bill would not in the least degree improve the position of Dr. Herz, because

it was quite obvious that if he was too ill to leave his bed he was too ill to be examined by a magistrate. The Bill referred to was read a second time the same evening in the House of Lords. In explaining its purpose the Lord Chancellor said that under the Extradition Act if a person charged with an extradition offence was too ill to be conveyed to Bow-street, London, there was no means of holding an inquiry at all, even though the person charged might be well enough to be present at the inquiry. The Bill proposed that in these circumstances the Secretary of State should have power to order an inquiry elsewhere than at Bow-street.

The Debate on the Opium Question.

The sitting of the House between nine o'clock and midnight was devoted to a debate on the opium question. The subject was introduced by Sir Joseph Pease, who moved the following resolution—viz.: "That this House, having had before it its resolution of June 30th, 1893, pressing on the Government of India to continue their policy of greatly diminishing the cultivation of the poppy and the production and sale of opium, and having had presented to it the report of the Royal Commission appointed Sept. 2nd, 1893, to inquire into various matters connected with the cultivation of the poppy in India, is of opinion that the system by which the Indian opium revenue is raised is morally indefensible, and would urge upon the Indian Government that they should cease to grant licences for the cultivation of the poppy and sale of opium in British India, except to supply the legitimate demand for medical purposes, and that they should at the same time take measures to arrest the transit of Malwa opium through British territory." Sir Joseph Pease said he wished to seize the opportunity of endeavouring to remove the impression which appeared to prevail in many quarters that this Royal Commission had terminated for ever the question of the trade in opium, that it had met the views of those who had been opposed to this trade, and who had for many years fought against its continuance in our Indian Empire. They still held to the opinion that the system by which this revenue was raised was morally indefensible, and he asserted that the report of the Commission confirmed the view that this trade was morally indefensible. On the appointment of the Commission he had received assurances from Lord Kimberley that the inquiry would be a fair and free inquiry in India; but having obtained the Commission the Indian Government at once proceeded to dry-nurse it. They provided it with three consecutive secretaries previously in their pay, and he believed that at this moment these gentlemen were attached to the Government of India. Five ladies were attached to the Commission; there was a review of troops at which Lord Brassey, the chairman, nearly lost his life; and, in order to bring this great Commission on a moral question up to the mark, the whole of the members except his hon. friend behind him (Mr. Henry J. Wilson) were entertained at an Indian Nautch dance. A very high official of the Indian Government was attached to the Commission for the purpose of bringing up the evidence. The evidence was collected by Mr. Dane; a large quantity of it passed through the hands of the Calcutta Government; but the anti-opium members were not aided to bring up a single witness. The whole power and money of the Indian Government were against the two subscribers to the anti-opium movement. He was struck by the manner and style—the Old Bailey style—in which Sir James Lyall put his interrogatories to the witness brought against the opium traffic, and anyone who read the evidence must be struck with its hearsay character and tone. It was, moreover, difficult to find out what the Commission had reported. There was little or no positive recommendation except on the question of smoking, and here it was suggested that the use of opium should be restricted. Then again the Indian Government thanked the Commission for their trouble because the inquiry held strengthened the hands of the Government. The Commission also thanked the two paid officers who were their secretaries for having drafted their report. No doubt the secretaries ought to have drafted the report, but ought they to have been in the pay of the Indian Government or ought they not rather to have been independent secretaries? He asserted that the report was settled in the India Office. Dealing in detail with the report, Sir Joseph Pease said that the paid officers of the Indian Government occupied 240 pages out of 392. Of the 130 medical men examined, 82 were official, 14 missionary, and 34 independent. Of the officials, 44 were favourable, 18 indifferent, and 20 unfavourable. All the missionaries were unfavourable to the use of opium and half of the independent medical men. He then quoted from the report to make good these positions—that as a febrifuge and prophylactic opium was not wanted, that the cultivator could do without it, that we could arrange with the native States, that the native soldiers were better without it, that opium smoking was condemned in India as a low and vicious habit, and that in China it was undermining society, while from its effects the people were surely deteriorating.—Mr. John Ellis seconded the resolution.—Mr. Fowler, Secretary of State for India, defended the Commission from the attacks made upon them. He explained the elaborate arrangements they made for their inquiry, and the number and the place of their meetings. They examined, he said, 723 witnesses, these including every witness offered by the Anti-Opium Society. They put something like 25,000 questions. They sent interrogatories to China and to the Straits Settlements. The report was signed on April 16th. It was placed on the table of the House of Commons on April 25th; it was delivered to members on May 4th; it was sent to India by the mail of May 10th; and now on May 24th, not three weeks from the date it was first placed in the hands of members, and while it was absolutely impossible for the Government of India to have read it, and the minority report contained a very serious censure upon that Government, this House was asked to declare that it was a prejudiced document, and that all the Commissioners save one were wrong, and one only was right; and between the hours of nine and twelve o'clock this House was asked to pass this resolution of censure of the greatest magnitude. Such a course was not fair to the Commissioners, nor to the people of India, nor to the Government of India, nor to the members of this House themselves. After referring to some of the qualifications for the work possessed by the members of the Commission, Mr. Fowler said that the discharge of this public duty involved a great amount of physical and mental labour. It was a thankless duty, but, after all, Englishmen were in the habit of treating men who did a public duty with the greatest generosity and the greatest consideration. It was said that these gentlemen went to dances of the Nautch girls and were entertained by the Viceroy. When they were told that because they were asked out to dinner they could not

deal with this case impartially, he must protest against this mode of dealing with a commission of this character. There was an end of Royal Commissions, which had hitherto been one of the most powerful and convenient modes of inquiry, if gentlemen discharging duties of Commissions were to be treated as those gentlemen had been treated. These Commissioners arrived at a series of distinct conclusions. They all admitted that the report of the Commission conflicted with many preconceived opinions. There was a new light thrown upon the whole of this case by the report. He was not going to say that his hon. friends were wrong and the Commissioners right, but questions had been raised affecting the opium consumption, affecting the opinions of missionaries and medical men, and he maintained that before the House of Commons gave a decision these questions must be argued out. Public opinion must be informed on the question and scientific opinion must be ascertained. The matter must be decided not by personal attacks upon the Commissioners, but by the weight and value of the evidence. His hon. friend said that the medical evidence was nearly equally divided. There were 146 medical witnesses examined, and of these only 20 were against the use of opium and 126 went the other way. Then the Government of India had a right to be heard before any decision was arrived at by this House. They would not treat any parish council in the manner in which his hon. friend proposed to treat the Government of 300 millions of people. He would leave this question, as Lord Beaconsfield said, "to the instinctive justice of the House," and he was sure that the House of Commons would not decide in such a manner. The Government objected to this motion because it was premature and because it was immature, because it involved a flagrant injustice on the one hand and because it was impracticable on the other. They were asked as a Parliament to reject the deliberate judgment of a competent commission, and to do so without the slightest opportunity of examining, much less testing, the evidence on which that judgment was founded. They were asked to deprive the Government of India of a large portion of its revenue without making any provision for the inevitable deficit which must follow, thereby involving one of two things—either disabling the Indian Government from meeting its engagements or necessitating the imposition of a heavy extra taxation.—Mr. Mowbray, one of the members of the Royal Commission, then addressed the House. He claimed that anybody who carefully studied the evidence would believe that the report they had given was a fair and impartial report, and the only report which they could possibly have given. There were certain heads of evidence for the presentation of which to the Commission the Government of India held itself responsible, but the rest of the witnesses were selected by the local governments because they were supposed to know best what persons were likely to give good evidence. The Government of India, instructing the local governments as to the selection of the independent and non-official witnesses, said: "It is desirable that they should be gentlemen of some social standing, of independence of character, and of good general intelligence, and so completely in touch with public feeling in their respective provinces as to command the respect and confidence alike of the people of India and of the members of the Commission." The local governments, he believed, did their work honestly in that way, and he also believed that the witnesses who were examined supplied a fair representation of the views of the people of India.—Mr. Henry J. Wilson, another member of the Commission, rose, but he had only addressed a few words to the House when the closure was moved and agreed to. Thereupon the division was taken, when 59 members voted for the resolution and 176 against it.

MONDAY, MAY 27TH.

Foreign Butter.

Mr. Herbert Gardner, replying to a question, said that arrangements had recently been made by which samples of butter would be taken at the ports of importation and analysed by the principal chemist of the Government laboratories, who was also the chief agricultural analyst. A certain number of samples had, in fact, already been taken, and he was in communication with the Treasury and the Board of Customs with a view to the settlement of the course to be pursued in the event of its being found that any offences under the Sale of Food and Drugs Acts, the Margarine Act, or the Merchandise Marks Acts, had been or were likely to be committed.

The Vaccination Commission.

Mr. Asquith said that all he could say about the publication of the final report of the Royal Commission on Vaccination was that the Commissioners were at present busily engaged upon the report, but that they could not say when it would be published.

TUESDAY, MAY 28TH.

Nursing in Workhouses.

Mr. Shaw-Lefevre, replying to a question, said that the Local Government Board were fully impressed with the importance of securing efficient nursing in workhouses by an adequate staff, and the Board had recently addressed a communication to all boards of guardians bringing this matter specially under their attention. They at the same time stated that, whilst they were not prepared to lay down as a rule that in no case should pauper inmates act as attendants in sick wards as clearly distinguished from nurses, they considered that their services should only be used with the approval of the medical officer and under the closest supervision at all times of paid officers.

IN COMMITTEE.

Food Products Adulteration.

The Select Committee of the House of Commons on the question of the Adulteration of Food Products resumed the examination of witnesses on Tuesday, May 28th, Sir Walter Foster presiding.

Mr. Haaleside, manager for Messrs. Colman, mustard manufacturers, of Norwich and London, said that when mustard seed came in from the farmers the first thing that was done was to clean and dry it. In the process of manufacture a great deal depended upon the proper separation of the husks. There were brown mustard seed and white mustard seed. The mustard condiment in general use was practically an admixture of the flour of those two seeds, with a slight colouring matter and a small proportion of wheat flour and chillies. The flour of the brown mustard seed was a perfectly pure

mustard. It was the most pungent. Its flavour, however, was too bitter to render it fit for actual use. They got considerably more flour out of the white mustard seed. When any customer required the brown mustard he was supplied with it; that mustard would not, however, bear export through the tropics. French mustard was made with the husks mixed with the flour of mustard and other ingredients which were not used in England. The process of mustard seed growing is understood better in England than anywhere else. Mustard could be made from very inferior foreign seeds, and would not be affected by the Adulteration Acts. He recommended that public analysts should have a chemical rather than a medical training.

Sir William Pink, J.P., Knight of the Legion of Honour, of the Grocers' Federation, said he had had great experience of the grocery and provision trade, and he expressed the opinion that an invoice sent by a wholesale merchant to a retailer should be sufficient to hold the latter free from prosecution.

The Committee again adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ARNOLD, G. J., L.R.C.P., M.R.C.S., has been reappointed House Surgeon to St. Thomas's Hospital.

BLOUNT, G. B. C., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Ear at St. Thomas's Hospital.

BRACKENRIDGE, F. J., L.R.C.P., M.R.C.S., has been reappointed Non-Resident House Physician to St. Thomas's Hospital.

BRANSON, GUY J., L.R.C.S., L.R.C.P. Edin., L.S.A. Lond., B.A. Lond., has been appointed House Surgeon to the Queen's Hospital, Birmingham.

CANDLER, G., B.A. Camb., L.R.C.P., M.R.C.S., has been appointed Junior Obstetric House Physician to St. Thomas's Hospital.

CARTER, A. H., M.D. Lond., F.R.C.P., M., M.R.C.S., has been appointed Honorary Consulting Physician to the Smallwood Hospital, Redditch.

CLARK, FRANCIS W., M.B. Durh., D.P.H. Camb., M.R.C.S., L.R.O.P. Lond., has been appointed (by the Crown) Health Officer for Hong-Kong.

COLLIS, A. J., M.B., B.C. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer to the Weston-super-Mare Hospital and Dispensary.

CONFORD, G. J., B.A. Oxon., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Electrical Department at St. Thomas's Hospital.

CRAN, GEO., M.D., C.M. Aberd., has been reappointed Parochial Medical Officer for Banchory.

DANIEL, E. G. C., L.R.C.P., M.R.C.S., B.A. Camb., has been appointed Resident House Physician to St. Thomas's Hospital.

DAVIS, H. J., M.A. Camb., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

DIXON, W. E., B.Sc. Lond., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Electrical Department at St. Thomas's Hospital.

DUMHILTON, C. E., M.A., M.D. Camb., M.R.C.S. Eng., D.P.H., has been appointed Surgeon to the Dalby Hospital, Queensland.

DURRANT, T. A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Market Harborough Urban Sanitary District, vice Allen.

EGAR, R. T. S., M.D. Edin., M.R.C.S., has been appointed Medical Officer of Health by the Stourbridge Urban District Council.

EMERY, W. D'ESTE, M.R.C.S. Eng., L.R.C.P. Lond., B.Sc. Lond., has been appointed House Physician to the Queen's Hospital, Birmingham.

GENGE, G. G., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Ear at St. Thomas's Hospital.

HAINES, AUBREY WHEELER, L.S.A. Lond., B.Sc. Lond., has been appointed Obstetric and Ophthalmic House Surgeon to the Queen's Hospital, Birmingham.

HARDING, H. W., L.R.C.P., M.R.C.S., has been reappointed House Surgeon to St. Thomas's Hospital.

HORNE, THOMAS, M.D. Durh., L.R.C.P. Edin., L.R.C.S., has been appointed Medical Officer for the Borough of Stockton and Medical Superintendent for the Stockton Fever Hospital.

HUDSON, C. E. L., F.R.C.S., L.R.C.P. Lond., has been appointed Assistant Surgeon to the Middlesex Hospital.

HUGHES, JOHN E., M.D. Edin., M.R.C.S., L.S.A., has been appointed Coroner for West Denbighshire, vice Evan Pierce, deceased.

HUGHES, R. JAMES, M.B., B.S. Durh., L.S.A., has been appointed Honorary Surgeon to the Denbighshire Infirmary and Dispensary.

HUXLEY, F. E., M.R.C.S., L.D.S.R., C.S. Edin., has been appointed Honorary Consulting Dentist to the Smallwood Hospital, Redditch.

JENNER, L. L., M.A., M.B., B.Ch. Oxon., M.R.C.P., has been appointed Resident House Physician to St. Thomas's Hospital.

KIRK, T. S., M.B., B.Ch. Irel., has been appointed Assistant Surgeon to the Belfast Hospital for Sick Children.

LAVIE, J. W., L.R.C.P., M.R.C.S., has been reappointed Non-Resident House Physician to St. Thomas's Hospital.

LISTER, S. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the fourth and fifth Sanitary Districts of the Wisbech Union, vice Seccombe.

LYNASS, J., M.B., B.S. Irel., has been appointed Resident Physician to the Union Hospital, Belfast.

MCARDY, JAMES, L.F.P.S. Glasg., has been reappointed Parochial Medical Officer for Banchory-Ternan.

MATHEWS, B., L.R.C.S. Irel., has been appointed Honorary Medical Officer to the Smallwood Hospital, Redditch.

MAY, B., F.R.C.S. Eng., has been appointed Honorary Consulting Surgeon to the Smallwood Hospital, Redditch.

MILWARD, F. V., B.A., M.B., B.C. Camb., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.

MORTON, E. M.D. Edin., C.M., has been appointed Honorary Medical Officer to the Smallwood Hospital, Redditch.

PAGE, H. M., M.D. Brux., M.R.C.S., D.P.H. Camb., has been appointed Honorary Medical Officer to the Smallwood Hospital, Redditch.

PATRICK, J., M.B., B.S. Irel., has been appointed Resident Surgeon to the Belfast Union Infirmary.

PRICE, J. E., M.R.C.S., has been appointed Honorary Medical Officer to the Smallwood Hospital, Redditch.

PORTER, W. E., M.D., M.S. Edin., M.R.C.S., D.P.H. Camb., has been appointed Medical Officer to the Printers' Almshouses, Wood Green.

PRIN, J. L., L.R.C.P., M.R.C.S., has been reappointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

RICHARDSON, S. W. F., M.B., B.S., B.Sc. Lond., L.R.C.P., M.R.C.S., has been appointed Senior Obstetric House Physician to St. Thomas's Hospital.

ROCHE, ANTONY, M.R.C.P. Irel., has been appointed Professor of Medical Jurisprudence and Hygiene in the Catholic University Medical School, Dublin.

RUSSELL, A. E., M.B. Lond., L.R.C.P., M.R.C.S., has been reappointed House Surgeon to St. Thomas's Hospital.

SECOMBE, P. J. A., L.R.C.P., M.R.C.S., M.A. Camb., has been appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

SENGWICK, H. R., B.A. Camb., has been appointed Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.

SHEEHAN, JOHN, L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Health for the Southrepps Sanitary District of the Eppingham Union.

SMITH, W., M.R.C.S., has been appointed Honorary Medical Officer to the Smallwood Hospital, Redditch.

SMITH, C. C., M.B. Camb., M.R.C.S., has been appointed Honorary Medical Officer to the Smallwood Hospital, Redditch.

STEEN, WM. C. M.D., M.Ch. H.C.U.L., has been appointed Hon. Assistant Physician to the Belfast Hospital for Sick Children.

STEPHEN, JAMES, M.D., C.M. Aberd., has been appointed Parochial Medical Officer for Peterhead.

STONE, W. G., M.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

SWICK, E. H. W., M.D. St. And., M.R.C.S., D.P.H. Camb., has been reappointed Medical Officer of Health for the Droitwich Rural Sanitary District.

SYMONS, CHARLES J., M.S. Lond., F.R.C.S. Eng., has been appointed Consulting Surgeon to the London and South-Western Railway Servants' Orphanage, vice A. E. Durham, deceased.

SYMONS, R. FOX, L.R.C.P., M.R.C.S., has been reappointed House Surgeon to St. Thomas's Hospital.

TAYLOR, E. H., M.B., B.Ch. Dubl., has been appointed to the Surgical Staff of the Sir Patrick Dun's Hospital, Dublin.

TOOMBS, H. G., L.R.C.P., M.R.C.S., has been appointed Senior Ophthalmic House Surgeon to St. Thomas's Hospital.

TREB, JOHN F., M.R.C.S., has been appointed Medical Officer for the North-Eastern Sanitary District of the Greenwich Union, vice Nicholson.

TURNER, GEORGE, M.B. Camb., D.P.H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Government of the Cape of Good Hope.

WAKELAM, EDGAR, L.R.C.P., L.R.C.S., &c., has been appointed Medical Officer of Health for the Springhead Urban District of the West Riding.

WALLIN, FRED. C., M.B., B.C. Cantab., F.R.C.S., has been appointed Surgeon to the Out-patients at Paddington-green Children's Hospital.

WATKINS, A. M., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Workhouse and the Whitechurch Sanitary District of the Whitechurch Union, Salop, vice George.

WATTS, BRIAN, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon to the Children's Hospital, The Wicker, Sheffield.

WRIGHT, J. F., M.R.C.S., has been appointed Medical Officer for the West Bolton Sanitary District of the Bolton Union, vice Morris.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—House Physician for six months. Board, residence, and allowance for washing provided. Applications to the Secretary, Office, 24, Finsbury-circus, E.C.

DERBY COUNTY ASYLUM, Mickleover.—Second Assistant Medical Officer, single. Salary £100 a year, increasing £10 annually to £130, with board (except beer), lodging and washing.

EVERINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, S.E.—Senior Resident Medical Officer. Salary £70, with board and washing. Also Junior Resident Medical Officer. Salary £50, with board and washing.

GLAMORGANSHIRE AND MONMOUTHSHIRE INFIRMARY, Cardiff.—Assistant Resident Medical Officer, for six months. Board, washing and apartments provided.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury, W.C.—House Surgeon to Out-patients (non-resident), for six months. Salary 25 guineas.

KENSINGTON DISPENSARY.—Resident Medical Officer, unmarried. Salary £125 per annum, with furnished apartments, coal, gas and attendance. Applications to the Honorary Secretary, 7, Stamford-road, Kensington-square.

LEICESTER INFIRMARY.—House Physician, for one year. Salary £80 per annum, with board, apartments, and washing. Also Assistant House Surgeon for six months. Board, residence at the Infirmary, and washing will be provided.

LONDON HOSPITAL, Whitechapel, E.—Medical Electrician.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.—Senior Demonstrator of Anatomy. Salary by a percentage on fees.

MANCHESTER ROYAL INFIRMARY.—Resident Medical Officer for one year, unmarried. Salary £150 per annum, with board and residence.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (ALBANY MEMORIAL), Queen-square, Bloomsbury.—Senior and Junior House Physician respectively. Salary of the former £100 per annum, and of the latter £50 per annum, with board and apartments, in each case, in the Hospital.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—House Physician for six months. Salary at the rate of £60 per annum.

PARISH OF BIRMINGHAM WORKHOUSE INFIRMARY.—Resident Assistant Medical Officer. Salary £100 per annum, with furnished apartments, rations (which do not include alcoholic liquors), coals, gas, washing, and attendance. Applications to the Clerk to the Guardians, Parish Offices, Birmingham.

PARISH OF LAMBETH.—Medical Officer for the Infirmary, Brook-street, the Workhouse, Renfrew-road, and the Workhouse, Prince's-road. Salary £300 per annum, with furnished house and allowance for coals, gas, and water. Applications to the Clerk, Guardians' Board-room and Offices, Brook-street, Kennington, S.E.

RAIDLIFFE INFIRMARY, Oxford.—House Physician, for six months. Salary at the rate of £60 a year, with board, lodging and washing.

ROYAL VETERINARY COLLEGE, Camden Town, N.W.—Lecturer on Biology (Botany and Elementary Zoology). Salary £100 per annum.

RURAL DISTRICT COUNCIL OF DROXFORD.—Medical Officer of Health for this rural district. Salary £125 per annum, to include travelling and all other expenses. Applications to the Clerk, Bishop's Waltham.

ST. LUKE'S HOSPITAL, London, E.C.—Clinical Assistant for six months. Board and residence provided.

SOMERSET AND BATH LUNATIC ASYLUM, Wells, Somerset.—Second Assistant Medical Officer, unmarried. Salary £100 a year, with board, lodging, and washing.

VESTRY OF LAMBETH.—Medical Officer of Health for the Parish. Salary £700 per annum, such salary to include the cost of a carriage to be provided by the officer. Applications to the Clerk to the Vestry, Vestry Hall, Lambeth.

Births, Marriages, and Deaths.

BIRTHS.

BARR.—On May 27th, at Wentworth, Rotherham, the wife of Horace Carlos Barr, M.R.C.S., L.R.C.P., of a daughter.

BRINTON.—On May 26th, at Queen's-gate-terrace, S.W., the wife of Dr. Roland Danvers Brinton, of a son.

CALEY.—On May 21st, at Castlebar-road, Ealing, the wife of Guthrie Neville Caley, M.D., of a daughter (stillborn).

CORNER.—On May 23rd, at Earlswood Asylum, Redhill, the wife of Harry Corner, M.D., of a son (premature, and only lived a few hours).

KINGSTON.—On May 20th, at Alsager, Stoke-on-Trent, the wife of Henry F. Kingston, B.A., M.B., B.Ch. Dubl., of a daughter.

MALDEN.—On May 25th, at Pembury, Tunbridge Wells, the wife of Walter Malden, M.A., M.B., of a daughter.

FARE.—On May 21st, at 18, Portland-place, W., the wife of J. W. Fare, M.D., C.M. Edin., and L.D.S. Eng., of a son.

PARKER.—On May 19th, at Rickmansworth, the wife of Charles A. Parker, F.R.C.S., of a son.

ROBERTSON.—On May 25th, at Hill House, Adderbury, near Banbury, the wife of Jas. S. Robertson, M.R.C.S., of a son.

RUSHWORTH.—On May 24th, at Langdale, Goldhurst-terrace, Hampstead, the wife of Frank Rushworth, M.D., of a daughter.

SCHOFIELD.—On May 25th, at Camberwell House, Camberwell, S.E., the wife of Frank Schofield, M.D., of a son.

WALTERS.—On May 26th, at 5, Fairfield-road, Croydon, the wife of F. R. Walters, M.D., M.R.C.P., of 60, Welbeck-street, of a daughter.

WIGHT.—On May 22nd, at The Cannons, Colchester, the wife of Surgeon-Major E. O. Wight, A.M.S., of a daughter.

MARRIAGE.

HAGUE-HAMES.—On May 23rd, at St. James's Parish Church, Bath, Samuel Hague, M.D., of Camberwell, to Emily, widow of the late J. Hames, Esq., of Queensland.

DEATHS.

ALFORD.—On May 28th, at Royal-crescent, Weston-super-Mare, George Ernest Alford, L.R.C.P. Edin., M.R.C.S. Eng., aged 42.

COWARD.—On May 25th, at his residence, at Knysna, Cape Colony, suddenly, Richard Courtenay Coward, M.R.C.S., L.R.C.P. Lond., aged 39.

TURNBULL.—On May 27th, at Camden-crescent, Bath, George Wardlaw Turnbull, M.D., L.R.C.S. Edin., aged 62.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians. 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY.—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Drs. Duncan, Playfair, Griffith, Lewers, Addinell, and Mr. O'Callaghan. Papers.—Dr. Eden: On the Development and Normal Structure of the Human Placenta, with limelight demonstrations.—Mr. Alban Doran: Placental Polypus.

THURSDAY.—NEUROLOGICAL SOCIETY OF LONDON (20, Hanover-sq.).—8.30 P.M. Drs. J. R. Lunn, C. E. Beevor, and C. A. Ballance: Case of Removal of Cerebellar Tumour.—Dr. Buzzard: Neuritis and Blocking of Brachial Artery.—Dr. Taylor: Case of Morphia in an Epileptic Patient.—Drs. Penrose and Beevor: Case of Schrodernia.—Dr. Hale White: A case in which Breathing is carried on by the Diaphragm only.—Dr. H. B. Donkin: Two cases of Friedreich's Disease.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Craig: Climacteric and Senile Insanity.

ROYAL INSTITUTION.—3 P.M. Professor E. Ray Lankester: Thirty Years' Progress in Biological Science (IV.).

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Gowers.

LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 8 P.M., Mr. A. Q. Silcock: Glaucoma, with Illustrative Cases.—Hospital for Skin Diseases, Blackfriars, 1 P.M., Dr. Payne: Urticaria and Allied Affections.

THURSDAY.—LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Gt. Ormond-st., 3.30 P.M., Dr. A. E. Garrod: Congenital Heart Disease.—National Hospital for the Paralyzed, Bloomsbury, 2 P.M., Dr. Taylor: Varieties and Treatment of Epilepsy.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Prof. Clifford Allbutt: Cases in the Wards.

ROYAL INSTITUTION.—3 P.M. Mr. William Huggins: The Instruments and Methods of Spectroscopic Astronomy (III.). (Tyndall Lecture.)

FRIDAY.—LONDON POST-GRADUATE COURSE.—Bacteriological Laboratory, King's College, 3 to 5 P.M., Prof. Crookshank: Actinomyces and Glands.

ROYAL INSTITUTION.—9 P.M. Professor Alfred Cornu: Phénomènes Physiques des Hautes Régions de l'Atmosphère.

SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Percy Smith: Alcoholic Insanity.

ROYAL INSTITUTION.—3 P.M. Professor Edward Dowden: Elizabethan Literature (II.).

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular in question.

TOUTING FOR PATIENTS.

WE have received from a correspondent a letter enclosing the following enterprising communication:—

"May 29th, 1896.

"DEAR SIR!—I take the liberty of calling your attention to the fact that I am practising as a physician at Carlsbad, having been formerly under the care of the famous Specialist Professor Osier, of Vienna, and I will now be in the position to give consultations, in the English language, in all cases of Diseases of the Stomach, Intestines and Liver, and in Diabetes etc. I will be greatly pleased to answer any enquiries about Carlsbad, as to the qualities of the place, the conveniences of living, the climate, hotel-rates etc. I shall be very much obliged to my colleagues, if they will shew me their confidence, when sending patients to Carlsbad, by committing them to my care, and I have reason to hope that the patients themselves will feel satisfied in every particular, and this the more as I can speak English with perfect fluency, having spoken it from my childhood, and having done much work as a Vienna Correspondent of English Medical Journals.

"I beg you, dear Sir, to believe me,

"Yours most respectfully,

"Dr. L. L."

Sir.—If our correspondent is satisfied that the classes of persons to be attended are entitled to be attended on club terms he may be justified in offering to attend them. As to the terms on which he should offer to do so he is the best and only judge, knowing the means of the people, the distances, and the remuneration for like work in the district. He should be careful not to make his services too cheap.

Mr. Edward C. B. Ibbotson, L.S.A.—Views on the subject which our correspondent suggests have already been expressed in our columns. We may refer him to the article on page 259 of THE LANCET of Jan. 26th, 1895.

STRANGE REMEDIES.

To the Editors of THE LANCET.

SIRS,—I am curious to know if the following remedy is in vogue elsewhere. A child has thrush, and at the advice of certain septuagenarian ladies, less cleanly than clever, a frog is hung head downwards in the patient's mouth until the reptile dies. One man boasted his little son had "wore out" four. Last of all, in this particular case the child died also, but from convulsions. Have babes in other neighbourhoods, I wonder, to undergo this very disagreeable line of treatment?

I am, Sirs, yours faithfully,

H. GUTHRIE.

Clun, Salop, May 27th, 1896.

THE MIDWIVES REGISTRATION BILL.—LOCAL DEPUTATION TO
BARON DE WORMS.

THE *Liverpool Daily Post* reports that a large deputation of medical gentlemen waited on Baron De Worms, M.P. for East Toxteth, to explain their objection to the Bill, and begging him to offer opposition to it in the House of Commons. Dr. Rentoul and Mr. Campbell were the principal speakers. Baron De Worms, who had passed two years in a medical school, agreed with the deputation, and said they might depend on him to adopt any practicable means to prevent it becoming law.

Corabill.—We are unable to support our correspondent in his action in withholding the certificate. The fee he asks for is for the performance of the vaccination. It appears to us that the method of payment by instalments is calculated to land him in the difficulty he has now encountered. The Vaccination Act requires that the vaccinator shall return a certificate of successful vaccination, and this has obviously no reference to the arrangement under which the vaccination was performed. If a parent is unable to afford the small sum mentioned she should take her child to the public vaccination station.

Medico.—We have been unable to find our correspondent's name on the Register, and would for that reason suggest that his *nom-de-guerre* is not very well-chosen. We fail to see any points calling for comment in the case which he brings before us. The good "specialist" is surely not a person who may not be consulted at all save upon the subject to which he is, or is supposed to be, singly devoted.

"MEDICAL ADVERTISING AT HARROGATE."

To the Editors of THE LANCET.

SIRS,—I quite agree with what you say about advertising; but I find that Dr. A. S. Myrtle, J.P., and Dr. J. A. Myrtle, J.P., advertise their book on the Harrogate Waters. I also find that both these medical men have been presidents of the Harrogate Medical Society, and I naturally concluded that their action was concurred in by all the medical men of Harrogate; hence I decided to insert my advertisement. Drs. A. S. and J. A. Myrtle's advertisement is often accompanied by an extract from THE LANCET or some other medical paper. I therefore took the liberty to insert one of your remarks on my pamphlet. I forward to-day's paper with the above-mentioned book advertised in it, and an extract from THE LANCET. If, however, the medical men who have thus far supported their late presidents, who advertise their book, will get Drs. Myrtle to stop their advertisements I will stop mine.

I am, Sirs, yours sincerely,

Princes-square, Harrogate, May 25th, 1895. ARTHUR ROBERTS.

To the Editors of THE LANCET.

SIRS,—Thanks for calling my attention to the advertisement in the Harrogate paper. I have nothing to do with it. The editor of the paper published the book, and maintains that he has a right to advertise it in his own paper. I am not going to try this right by legal proceedings, although I regret that this act on his part may give offence to such narrow-minded people as your informant. I do not see how I can put a stop to it.

I am, Sirs, yours truly,

Harrogate, May 21st, 1895.

A. S. MYRTLE.

. We insert the above letters, and note that Dr. Myrtle considers himself quite without responsibility for the advertisement, and that he has no intention of questioning the right of the editor of the paper to do as he likes. We can only regret that Dr. Myrtle should so have put himself in the power of an enterprising publisher. A medical author owes it to himself and to the profession to part with his book only on such terms as prohibit anything that looks like personal advertisement. An objector is not necessarily narrow-minded, and we hope that both Dr. Myrtle and Dr. Roberts will do all they can to stop these advertisements.—ED. L.

CHARGE AGAINST A MIDWIFE.

THE borough magistrates of Sunderland have lately had before them a case in which a midwife was accused of having persisted without change of clothes in attending cases of lying-in women during her attendance on a case of puerperal fever, and after being warned by Mr. Wood, the medical officer of health. In one of the cases so attended puerperal fever occurred. Mr. Wood asked the bench to inflict a fine. On the defendant promising not to attend a case for two months the bench allowed her to go free, with the understanding that if she violated this undertaking she would be brought up again on this charge.

LONGEVITY.

To the Editors of THE LANCET.

SIRS,—Commenting on the longevity of man in one of your interesting leading articles of last week you quote from the Book of Ecclesiasticus to show that an old estimate "gave a man's days as possibly 100 years."

I would beg to mention that there are besides some remarkable passages in Isaiah bearing on the same subject. The prophet, speaking of a time that is coming, says: "There shall be no more thence an infant of days, nor an old man that has not filled his days; for the child shall die an hundred years old." And again: "For as the days of a tree are the days of my people."

I am, Sirs, yours truly,

Lincoln, May 27th, 1895.

WILLIAM O'NEILL, M.D. &c.

COÖPERATION WITH QUACKS—SEQUAH OR OTHER.

A CORRESPONDENT has brought a charge against a medical man in Ireland before his College—the Royal College of Surgeons in Ireland—of cooperating with Sequah, being constantly at his meetings, on his platform, &c. This does seem very remarkable conduct for a member of a College which prides itself on its high spirit of professional honour. But the College has replied to the following effect: "The Council have had Dr. —'s letter before them, and are of opinion that the alleged conduct of — does not require any action on their part." We cannot go behind the judgment of the College. We can only infer that they have thought the proofs of the offence insufficient.

In the Parliamentary Report in our issue of May 18th a statement by Mr. Leckie, in his evidence before the Committee on Food Adulteration, was omitted, the statement being as follows: That he (Mr. Leckie) had Dr. Ringer's authority for saying that the application of certain quotations from his (Dr. Ringer's) book on Therapeutics could not possibly be taken to apply to Van Houten's Cocoa. A written authority from Dr. Ringer was handed in to the chairman.

UTERINE STEMS.

To the Editors of THE LANCET.

SIRS,—The endless variety of uterine stems clearly indicates their failure to accomplish their intended purposes, and justly accounts for their gradually falling into disuse. Without, however, pretending to have solved the difficult question of a perfect stem, I think I may lay before the profession a simple and, as far as I know, the most useful of uterine stems—one which in the hands of a practical gynaecologist affords him a means of not only dilating, but also of maintaining in a state of dilatation, and for as long as he may desire, the cervix uteri without the aid of an anæsthetic, in his own consulting-room when preferable, and without pain. This is accomplished by the aid of a series of five-graduated stems, each having a central hole through its long axis, the diameter of the hole in the largest stem being a quarter of an inch. It is through this hole that the practitioner can make repeated applications, as often as deemed necessary, of those medicaments which he may consider most suitable for the cure of a host of diseases incidental to the uterus and its appendages, such as endometritis, metritis, hypertrophy, perimetritis, salpingitis, ovaritis, &c. In the largest of these stems will also be found the most convenient means of alleviating the sequelæ of acute ante-flexion without the aid of the knife. I shall be pleased to show the stem to any member of the profession.

I am, Sirs, yours faithfully,

Peckham, May 11th, 1895.

ROBT. HUGH HODGSON.

. We feel bound to point out that intra-uterine stem pessaries had their origin in the false pathology which attributed an altogether exaggerated, not to say imaginary, importance to the necessity of keeping the axis of the uterus straight. It is difficult to understand how anyone can suppose that applications to the endometrium through a hole in the centre of a stem pessary can have any good effect on salpingitis. On the other hand, there is no doubt whatever that endometritis, metritis, perimetritis, salpingitis, ovaritis, and death, by which we may be allowed to translate our correspondent's " &c.," have been caused by the use of intra-uterine stems.—ED. L.

UN SOUND MEAT.

HENRY TAYLOR CAIRNS, a butcher in Sunderland, has been fined £2 and costs for exposing for sale unsound meat. Inspector Downes, a butcher himself, said the meat had been killed a fortnight at least. The "muggy" weather was blamed for the state of the meat.

Mr. S. Wesley Wilson.—We cannot see any internal evidence in the paragraphs that the practitioner in question has the remotest responsibility for their wording.

"AN OPHTHALMOLOGICAL HINT."

To the Editors of THE LANCET.

SIRS,—I am informed by Mr. Sydney Stephenson that the method of applying solutions to the conjunctive which I mentioned in your journal of the 18th inst. had been previously described by him in a book called "Ophthalmic Nursing." Of this at the time of writing I was unaware.

I am, Sirs, yours faithfully,

Eversley, Hants, May 23rd, 1895.

F. HYDE MABERLY, M.D. Dub.

During the week marked copies of the following newspapers have been received:—

Court Journal, Irish Times, Bedford Advertiser, Sheffield Weekly Telegraph, Chicago Daily News, Hobart Mercury, Wolverhampton Chronicle, Rochester Journal, West Lothian Courier, Halifax Guardian, Hornsey Journal, New Zealand Mail, Barnet Press, Adelaide Observer, Macleod's Courier, Birmingham Gazette, Eastern Morning News, South Australian Register, La Presse Médicale (Belge), Sunderland Herald, North-Eastern Daily Gazette, Australasian Medical Gazette, South American Journal, Harrogate Advertiser, Guy's Hospital Gazette, New York World, Cumberland Advertiser, Buxton Herald, Journal of the Royal Institute of British Architects, Fame, Reichs-Medicinal Anzeiger (Leipzig), Devon and Exeter Daily Gazette, Melbourne Argus, Banffshire Advertiser, Lynn News, Bury Times, Elgin Courant, Auckland Weekly News, &c. &c.

Communications, Letters &c. have been received from—

Terms for Position Pages and Serial Insertions on application.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 2, Rue Traversière, Amiens, Paris.

Lecture

ON

STAMMERING AND OTHER IMPEDIMENTS OF SPEECH, AND THEIR TREATMENT ON PHYSIOLOGICAL PRINCIPLES.

A Post-Graduate Lecture delivered at the Hospital for Sick Children, Great Ormond-street, on May 16th, 1895,

By W. S. COLMAN, M.D., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE HOSPITAL; PATHOLOGIST TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, ETC.

GENTLEMEN,—The subject of impediments of speech is one which receives scant attention in the ordinary text-books of medicine, being too often regarded as lying outside medical practice and as beyond the resources of therapeutics. The treatment of sufferers is almost entirely relegated to lay "professors" of elocution and voice culture, each with his secret "system" of cure. It is, however, as unreasonable for a physician to ignore and refuse to treat these complaints, and to hand them over to laymen, as it would be for a surgeon to refuse to undertake the treatment of deformities and to leave them to the instrument-maker. You will find that these affections possess considerable scientific interest, and that patient, intelligent, long-continued treatment on definite physiological principles will remove them in many cases and make them less prominent in almost all. It is unnecessary to enlarge on the serious disabilities caused by a marked stutter. Not only is it irritating to the patient's associates, but the consciousness of it in a sensitive individual may keep him from many social engagements, close up for him many ways of earning a living, and often make him morbidly self-conscious and timid. In order to understand clearly the character and mode of production of the various defects of speech, which are usually in this country classed together under the common name of "stammering," it is necessary in the first place to have a clear idea of the processes in normal speech. For the production of articulate speech we require the orderly coöperation of three muscular mechanisms, each of great complexity, and with a nerve supply which is by no means simple. These are: (1) the respiratory apparatus, for supplying a blast of air; (2) the larynx, for transforming this blast of air into voice; and (3) the musculature of the tongue, lips, and palate, for so modifying the voice as to give rise to different sounds which may be combined into words. Not only must the component muscles of each of these most delicate mechanisms act in perfect concert, but there must be also a coördination of the three mechanisms with one another, and if there is any failure of such coördination the various forms of stammering will be produced.

For the proper understanding of the defects of speech we require to construct another alphabet. The English alphabet, as grammarians tell us, is both defective and redundant, and it is necessary to reconstruct it on a phonetic basis, the letters being further grouped according to the position in the mouth, &c., where the voice is modified to produce the various consonantal sounds. The most convenient and complete alphabet is that given below, which was devised by my former teacher, Dr. John Wyllie of Edinburgh, whose views on the subject, given in his recent work,¹ have in the main been followed in this lecture.

Physiological Alphabet (Wyllie).

	Voiceless oral consonants.	Voiced oral consonants.	Voiced nasal resonants.
Labials	{ P —	B W	M —
Labio-dentals	F	V	—
Linguo-dentals	{ Th S	Th Z	— —
Anterior linguo- palatal	{ Sh T Ll —	Zh D L R	— N — —
Posterior linguo- palatal	{ K Ch (hard)	G —	Ng —

¹ Disorders of Speech. Edinburgh: Oliver and Boyd. 1894. No. 3745.

It will be noticed that in the physiological alphabet a distinction is drawn between "voiced" and "voiceless" consonants, which we shall see is of great importance in considering treatment. In the former, sound is produced simultaneously in the larynx each time the consonant is produced; in the latter there is merely an almost noiseless blast of air. B is an example of the former, P of the latter. This grouping corresponds to the grammarians' division of the letters into "sharp" and "flat." The voiceless group contains the "sharp" consonants, the voiced contains the flat consonants plus the nasals. Many find some difficulty in realising what is meant by "voiced" and "voiceless." The best method of demonstrating it was suggested by Dr. Wyllie. Let them pronounce slowly in a monotone the word "wonder," in which all the letters are voiced. The vocal element produces a continuous murmur, which can be extended indefinitely by merely repeating the word—"wonder, wonder, wonder," &c. If now the syllable "ful," containing the voiceless consonant "f," be added, and the word "wonderful" be pronounced in a similar way, a break will occur in the vocalisation of the word which will be at once obvious to the ear.

Coming now to the actual impediments of speech, we find that they may be divided into two groups: (1) spasmodic cases, familiar under the name of "stuttering"; and (2) cases where there is inability to produce particular sounds clearly. In its simplest form this is known as lisping, and may be due to clumsiness and pass off if the child is made to pay attention to it. Sometimes, however, it is due to structural defects in the mouth, and is then more difficult to treat, and in an important group of cases, described by the late Dr. Hadden under the name of "idioglossia," the patient substitutes for the letters he has difficulty in pronouncing some easier one—most frequently D or T. In most English works both groups are confused under the common term "stammering." In Germany "stammering" refers only to cases in the second group, those in the first being cases of "stuttering." In a few cases we find both conditions present, but the German grouping seems to me to be reasonable and well-founded. To avoid confusion the ambiguous word "stammer" will be used as little as possible during this lecture.

I.—STUTTERING.

This affection, distressing to the patient and irritating to his companions, is found in all degrees of severity, and may be represented only by slight hesitation in commencing to speak, or there may be violent, fruitless efforts to articulate, combined with associated movements of the muscles of the face and limbs, so extensive as to resemble a convulsion—a resemblance which is heightened by the engorgement of the vessels of the face caused by the violent expiratory efforts. These latter cases are fortunately rare. Stuttering is a widely spread complaint. Frequent allusions are made to it in ancient history, and at the present day it is prevalent in all parts of the world. It is met with among the negro races of Africa and is common among the Mongolian inhabitants of China, where it has been given the suggestive name of "kobi-ko." For some unexplained reason it is twice as frequent among males as females. Although stuttering is often met with in individuals whose mental capacity is far above the average, yet there is reason to believe that the proportion of sufferers is higher among epileptics and among those of defective mental development than among ordinary people, and that the prognosis in these subjects is less hopeful. The affection is rarely congenital. It usually comes on either in early childhood or not infrequently begins with some epoch in a child's life, such as the first going to school, period of second dentition, puberty, and so forth. Cases are not infrequently met with in which a child who has been a stutterer and recovered relapses on going to a boarding school. A well-known physiologist, who had almost completely mastered the defect, found it return to a distressing degree on going to live abroad, where he had to converse in an unfamiliar language. Generally speaking, there is a slight natural tendency to spontaneous recovery, but this recovery may be expedited and years of discomfort avoided by appropriate treatment.

Causation.—Although stutterers are frequently timid and morbidly self-conscious, this appears to be the effect rather than the cause. Hereditary tendency does not appear to play a large part in causation. Many cases that have been described as hereditary were probably cases of imitation of the parent. Imitation of other people's stutter is one of the commonest exciting causes, especially

in the cases where stuttering begins in early childhood. In many cases stuttering is first noticed after some infectious disease, notably diphtheria, a disease which has its seat in the articulatory apparatus. Adenoid vegetations in the nasopharynx are a frequent complication, but malformations of the mouth &c. are rare. The phenomena of simple stuttering are familiar to every one. It is in almost all cases the laryngeal and articulatory mechanism whose action is ill-timed. In rare cases, however, the respiratory muscles are in a state of spasm, and the patient stands, with glottis open but with the chest fixed, unable to emit a sound. In other cases, also infrequent, the larynx is the organ chiefly at fault, and the glottis is kept closed. The patient makes violent expiratory efforts, becoming red in the face, when suddenly vocalisation commences and he speaks rapidly. But in the great majority of cases the defect is due to two causes: (a) spasmodic action of certain muscles concerned with articulation; and (b) imperfect synchronism of the action of the laryngeal and articulatory mechanisms. It is by paying attention to this latter factor, as will be shown later, that the best results of treatment are obtained. On listening to the conversation of a stammerer you at once observe that he does not have equal difficulty with all consonants, and that those on which he stutters give difficulty only when occurring as the initial letter of a word or more rarely when commencing a syllable. Stuttering on vowels is very infrequently met with. When he comes to one of his stumbling blocks he makes evident attempt to pronounce it, but in the majority of cases remains silent. Occasionally he manages to pronounce the consonant and then keeps on repeating it, talking, for example, of a b-b-b-bath b-b-bun. This form, although so frequently met with in fiction and in anecdotes, is decidedly less frequent than the silent form. When once the difficult sound has been produced the words tumble out rapidly in a jerky way, "like water being poured out from a bottle," until the flow is checked by a fresh stutter. This curious, jerky mode of speech frequently persists when the stammer has been overcome, and may even last during the whole of the patient's life. Stuttering is always increased by excitement, dread, or any strong emotion, and by alcohol. Even in a healthy person stuttering is common under the influence of strong emotion—"speechless with anger" and "stammered out a few words of apology" are expressions which we frequently meet with, and which we probably know by experience to be accurate descriptions. This simple stutter, this inability to pronounce initial consonants, is, however, a mild affliction compared with those forms in which there are either associated sounds or associated movements. In the former case the noise made may only be an exaggeration of the "er" interpolated by many nervous and hesitating speakers, or more unpleasant noises may be made. One of my patients, when coming to a difficult consonant, would purse his lips up tight and keep up an unpleasant whimpering sound for five to ten seconds, when the word would be suddenly ejaculated. Sometimes the noises made are ineffectual but recognisable efforts to pronounce the consonant. It is curious that stammerers will never substitute another word for the one they have difficulty in pronouncing, even when it is suggested by a bystander, but persevere with increasing effort and discomfort to pronounce the word. But very often the sounds that are made were used in the first place to correct a stutter. A patient finds, for example, that by drawing in his breath and starting again he can avoid stuttering on the word which was giving difficulty. He gets in the habit of thus drawing in his breath, and not infrequently vocalises at the same time, so that a little whoop or crow—"drawback phonation," as it is called by Dr. Wyllie—is produced and interpolated in the patient's conversation. At other times some easy syllable or word (usually meaningless) is interpolated, such as "nana," "hedera," and this interpolation may persist when the stutter has disappeared. It has been unnecessarily described as a special complaint under the term "embololalia." Even more annoying to the patient's friends than these associated sounds are associated movements, which vary greatly as to their seat and their degree of violence. Most frequently they are confined to facial contortions, but occasionally there are gestures of the arms and hands. In a few exceptionally severe cases general convulsive movements of the trunk and limbs have been observed, leading the patient's friends to imagine that he was about to have an epileptic fit. These general spasms are usually accompanied by great congestion of the face and neck owing to the violent expiratory attempts made by the stammerer.

Treatment.—In treating a case it is most important to direct special attention to the above-mentioned associated sounds and movements as well as to the defects of articulation proper. In investigating any particular case the first thing is to ascertain the nature and extent of the articulatory defect and the presence or otherwise of associated movements or sounds. The most convenient method is to put down on a sheet of paper the "physiological alphabet" and ask the patient to read aloud half a page of prose (not poetry) or a paragraph from a newspaper. It is often well to choose some unfamiliar subject in order to bring out the stuttering thoroughly. As he reads attention should in the first place be given merely to the stuttering, and whenever he stumbles a mark should be made against the letter concerned. By the time he has read half a page we shall know whether the stuttering occurs with any particular group of letters, and the treatment can be directed accordingly. The patient then continues his reading, and we now notice if he is taking full breaths, if he speaks with a firm voice, and if there are any associated noises or movements. Note should be made of all these. We may then inquire if the patient stammers when singing, if the complaint is constant, and what circumstances aggravate it. The treatment of individual cases must vary with the age and intelligence of the patient and his individual circumstances, but general rules based on the physiological processes in speech may be applied in nearly every instance. It must be impressed on the patient and his friends that a sudden cure is out of the question, and that in patient perseverance lies the only hope of success. Everyone has heard of Demosthenes, stammerer and afterwards orator, and of the means he took to rid himself of the defect. The mode of treatment (by shouting with pebbles in the mouth) is not one to be recommended, but the means he adopted to force himself to persevere with treatment sets a valuable example. He retired to a lonely place to practise elocution, and, in order to strengthen his determination not to return till he had conquered, he shaved one half of his head. General treatment may be required if the patient is depressed, restless, or in any way out of health, but there is no drug known which has any specific influence. The patient should be instructed to keep his chest full of air when speaking. If his chest is small and breathing shallow much good may be done by daily exercising with dumb-bells or by practice in a regular gymnasium. When speaking he must endeavour to get into the habit of doing so in a clear, resonant voice, and must not speak rapidly. This is usually extremely difficult for him, and several months of steady practice may be required before the desired end is obtained. He and his relations must be instructed in the processes concerned in articulation, and should be shown the position of the tongue, lips, &c. requisite for the production of each consonant. Exercises consisting of sentences containing as many as possible of the consonants with which he has difficulty should be given him to learn by heart and repeat frequently. He must remember that in ordinary speech vocalisation and articulation occur simultaneously, and when he comes to a difficulty he must try to vocalise and not concentrate his efforts fruitlessly on articulation. Thus in trying to say B U N he should think not only of framing his lips for B, but must also remember that it contains a vocal element, and try to pronounce this, when it will be found that the labial sound is produced without difficulty. Similarly, he if stumbles over such a word as P O R T he should think not merely of the voiceless letter P, but of vocalising the vowel O, and he will find it quite easy to cap on the P as the word is uttered. This method, which we owe to Dr. Wyllie, has been of more help to those of my patients who were intelligent enough to understand it than any other. There is, however, necessity for a caution. Several patients had already found for themselves that by vocalising they could check a stutter, and so had got in the habit of making a meaningless noise before difficult consonants, making their conversation more unpleasant than ever. The patient should be warned that the laryngeal sounds must be appropriate, consisting either of the vocal element of the consonant he is about to utter or, if it is voiceless, of its succeeding vowel. It is important that not only the patient, but some member of his family, should be instructed in the principles of the treatment. The patient should be instructed to read aloud for at least half an hour twice a day, practising every difficult word in the way described above until its utterance becomes easy. A note should be made of each word which gives difficulty in order that it may be practised subsequently.

If there are any associated movements the reading practice should always be performed in front of a mirror, in order that he may become aware of and check any gestures.

II.—LISPING, IDIOGLOSSIA, &C.

In these cases we are dealing with defects in the articulatory mechanism only. They may be mechanical and due to oral deformities, or they may be due to clumsiness or in the use of the tongue, lips, &c., in which case the necessary skill can be acquired by patient practice. Such lispings are seen in all infants who are learning to talk, but the difficult letters are gradually acquired. In a few, however, there remains some defect in the pronunciation of particular consonantal sounds which may remain permanent and form quite a personal characteristic. Usually the sound which is produced is closely allied physiologically to the one which it is desired to pronounce, such as *w* for *v*, and *vice versa* (everyone will remember the use of this made by Dickens in giving individuality to some of the prominent characters in "The Pickwick Papers"); *R* and *L* are frequently interchanged by children, and *w* not infrequently is pronounced by children in preference to *R*—a preference which is imitated occasionally by affected adults. The same difficulties are met with in attempting to learn a foreign language. For a long time certain consonants present an insuperable difficulty, and are often never spoken with facility. The difficulties which Frenchmen have with the English *TH*, and which we experience with the German gutturals, and still more with those of Eastern languages, are an example of the same thing. The difficulties can only be got over by continued practice, but may be much aided by a knowledge of the correct position of the tongue &c. which is required for the production of the sound. Sometimes, however, the difficulty becomes insuperable, and the peculiarity of pronunciation becomes a racial characteristic. The most notable instance of this occurs in Jewish history, in the Book of Judges: "And it was so that when those Ephraimites which were escaped said, 'Let me go over,' that the men of Gilead said unto him, 'Art thou an Ephraimite?' If he said 'Nay,' then they said unto him, 'Say now Shibboleth'; and he said, 'Sibboleth,' for he could not frame to pronounce it right. Then they took him and slew him," &c. It is curious that at the present day this difference in the pronunciation of the sibilants *s* and *sh* forms one of the characteristics of the Jewish inhabitants of this country. In some cases, however, the affection is a more serious one. There is not only inability to pronounce several letters, but the substitution for them of totally dissimilar sounds, so that the patient's speech becomes quite unintelligible. These cases were described very clearly by the late Dr. Hadden in the *Journal of Mental Science* for 1889. He gave the affection the name of "idioglossia," and cases are by no means uncommon. I have myself full notes of eight cases in which the defect was well marked. Although the children are often intelligent and quick, the difficulty of making themselves understood gives other people the impression that they are idiots. In several of my cases there has been some other disease. One had an attack of right hemiplegia when five months old, which had left no permanent paralysis behind; another had a systolic and presystolic mitral murmur, and several came of a highly neurotic stock. The letters which cannot be pronounced include in almost all cases the posterior linguo-palatals, the labials and the linguo-dentals nearly always escaping. Next to the gutturals, *F*, *V*, and *B* appear to give most difficulty. The average number of consonants which my patients failed to pronounce was eight, and for these nearly all of them substituted *T* or *D*, the former for voiceless and the latter for voiced consonants. In some cases it was easier for the patient to pronounce consonants when they were terminal than when they were initial, a point of some importance in setting them vocal and reading exercises to enable them to overcome the disability. In investigating a case the child should be made to pronounce simple words of one syllable, first with the consonant under consideration as an initial, and then as a terminal letter, and note the result. It will then be seen at a glance to which part of the articulatory apparatus our attention should be directed. In all my cases the pronunciation of the vowels has been good and there has been no attempt at substitution. The following two cases well illustrate the condition.

CASE 1.—A boy aged six years was brought to me for defective speech. The notes are as follows: "Mental

condition distinctly above the average. His gestures and facial expression are so appropriate that it is usually quite easy to gather the sense of what he is saying, although the words are indistinguishable. When his speech is analysed it is found that he pronounces the vowels correctly except *o* in 'not,' which he pronounces 'naht.' He is unable to pronounce *F*, *V*, *S*, *Z*, *L*, *R*, *K*, or *G*, substituting for them the linguo-dentals *T*, *D*, or *N*. When he speaks rapidly he also substitutes *T* or *D* for many other letters, so that the words become quite unrecognisable. He says the Lord's Prayer in this fashion: 'Ouë tahde ne nah e nedde, anno de di na: i tede ta, i du de di on eeth a te e edde. Te ut te da ouë dade de, e didde ah tetedde, ä ne adin to tetedde adase us, ne notte tetate, ninné utte enu, to i arte nene, pouë e daude, to edde e edde. Ame.'" He could sing fairly well, but his articulation was as indistinct as when speaking. After about six weeks in hospital he improved greatly, and rapidly picked up and practised the methods for the clear pronunciation of the difficult sounds, except *K* and *G*, which he continued to express by *T* and *D*.

CASE 2.—This was a boy aged six years, a very nervous child. There was no deformity about the mouth. He pronounced the vowel sounds well. In speaking rapidly he substituted *T*, *D*, and *N* for most of the consonants. Even with an effort he could not pronounce all *F*, *V*, *TH*, *SH*, *R*, *K*, and *G*. His speech, therefore, was quite unintelligible, and as he was not quick at expressing himself by pantomime he had been supposed to be an idiot. He pronounced the Lord's Prayer thus: "Ouë dahde e ah edde, ayo be di na: i tede da, i ill be der o ert at it id e edde. Did ut it day ouë daidy ded, e diddu one destasses as ne didde da detass dast us, ed us not datadeh be deta us ede dor dis is de deda, pa de dorde, dow de ede. Ame." He was only under observation a short time. He learned to pronounce all the sounds at command, but could not be induced to use them correctly in ordinary conversation.

It was strongly insisted on by Dr. Hadden that these cases should be isolated from other children while under treatment. It is a comparatively easy thing to teach them the pronunciation of the consonants when making an effort, but it is a very lengthy and laborious business both for teacher and pupil to get them to use these correctly when speaking rapidly and automatically. However, the results obtained when time and patience are given to the work by some constant companions, such as a sister or a governess, who keep the child all day in their company, amply repay the trouble taken.

SALICIN AND SALICYLATES IN THE TREATMENT OF PSORIASIS AND SOME OTHER SKIN AFFECTIONS.¹

By H. RADCLIFFE CROCKER, M.D., F.R.C.P. LOND.,

PHYSICIAN FOR DISEASES OF THE SKIN, UNIVERSITY COLLEGE HOSPITAL.

THERE are so few drugs or other medicaments which when administered internally have any striking influence on diseases of the skin apart from syphilides that any addition to their number will, I am confident, be welcomed by the profession, especially by those who have not had the opportunity of availing themselves of the improvements in local treatment of modern dermatology. The undoubted success in many respects of this treatment which dermatology, like surgery, owes in great measure to antisepticism has had a tendency, coupled with the great authority of Hebra and the German school, to make us concentrate our efforts on directly affecting the cutaneous envelope, and to think comparatively little of what can be done by acting upon its contents. To those who have gone somewhat too far in this direction the discovery of the influence of thyroid extract on diseases of the skin must have been a rude awakening, and although, as usually happens, the limits of its efficacy are somewhat narrower than was at first hoped and believed, yet it was a startling reminder that the old humoral pathology, though buried, is perhaps not yet dead, and that a germ of truth still survives to bring forth a healthier and stronger plant than the original one. The drugs for which I am now claiming a not unimportant place

¹ This is a part of the introduction to a discussion on the Internal Therapeutics of Psoriasis at the annual meeting of the Dermatological Society of Great Britain and Ireland.

in cutaneous therapeutics have won an established reputation in other diseases, and this new field for their employment may give and receive assistance in our understanding the nature of the diseases in which they are useful, and to some extent their *modus operandi*.

The first case in which I gave salicylates was in that of a man aged thirty-two years, in whom psoriasis had only existed for a month, and who said that it came on two weeks after the commencement of a quinsy; the tonsils were still somewhat swollen at his first visit to the hospital on Dec. 8th, 1894. The well known association of tonsillitis and rheumatism induced me to give him salicylate of soda in fifteen-grain doses three times a day without any external treatment. The brief notes on the out-patient paper taken at the time state that the psoriasis was in round, defined patches on the arms, elbows, legs, chest, and abdomen. The patches were very abundant, bright red, and scaly, and had coalesced into large sheets of eruption on the chest and loins. At his next visit, a week later, I was astonished at the improvement. The patches had become much paler and most of the scales had fallen off. In another week improvement had continued and there was no longer any crusted scalliness left. The surface was paler, and by Jan. 19th, 1895—i.e., in six weeks—it was quite smooth and pale, except for a few fragments here and there; for these, on Jan. 26th, a resorcin ointment was given, and he did not attend again. Naturally this case led me to try salicylates much more extensively.

I will give an instance of psoriasis guttata thus treated. The patient was a woman aged twenty-eight years, who attended as an out-patient on Feb. 5th, 1895. She had been subject to the eruption off and on for fourteen years, was never absolutely free from it, and was generally worse every two years. The attack in question was recent and consisted of small spots from an eighth to half-an-inch in diameter, very abundantly distributed all over the limbs and trunk. Her father had suffered from gout, but she presented no evidence of gout or rheumatism. Fifteen grains of salicylate of soda in one ounce of infusion of quassia were given three times a day after meals. At her next visit, on Feb. 19th, it was noted that the eruption was much paler and that the scales had for the most part peeled off, even on the legs. The medicine in the same dose was continued, and on March 26th it was noted that the eruption had almost cleared off the legs, leaving very slight staining. The knee patches had entirely lost the hyperæmia, and the lower part was quite well, but there was some crusting at the upper part. A few small patches still had the remains of a scaly crust upon them, but when this was removed—and it was easily detachable—there was only very slight redness beneath. The eruption on the trunk had entirely cleared off, leaving very faint fawn-coloured stains. On the left forearm there was still a single patch the size of a florin, slightly reddened and rough, but there was very little crusting. Now, for the first time, a local application was given in the form of weak ammoniated mercury ointment, and she did not attend again.

Since these I have had several cases in which the result was equally striking and conclusive, and the form in which this was particularly so was in extensive spreading cases of psoriasis guttata of recent development—the very form which is usually unsuited both for thyroid extract and for arsenic, the former especially sometimes producing a very rapid extension and multiplication of the patches in this class of case. In cases where there were only a few chronic patches the result was not, as might be expected, so brilliant. Many of them distinctly improved, and some got quite well; but it is difficult to get patients to persevere with the same medicine for some weeks without having something to rub on, and I have always carefully abstained, where possible, from local treatment until quite the end of the case, when, the drug having amply proved its efficacy, a few remaining fragments of disease could obviously be at once removed by local treatment.

The first effect of the drug appears to be the diminution of hyperæmia, so that the patches become paler, the scales are no longer formed abundantly, and the old scaly crusts are detached or are easily detachable, exposing a pale red surface, which gets smoother week by week, and finally leaves only a slightly stained surface. I have not met with any case in which salicylate of soda aggravated the disease, with a slight exception of one who had been improving under its use, when I increased the dose to twenty-five grains three times a day. It produced gastro-intestinal irritation, and the eruption, which was very extensive and severe, began

to get more hyperæmic and crusted; but as soon as the drug was stopped and a gentian-and-soda mixture substituted the unpleasant symptoms passed off, he was soon able to resume his salicylate in fifteen-grain doses, and the disease again began to improve. He was a patient with extensive general psoriasis, which had on previous occasions gone on to pityriasis rubra.

In the case of a man aged thirty-nine years, with extensive psoriasis punctata, improvement was slow at first, but at the end of two months he only required a very little local treatment to remove the last traces of the disease. I have only used salicyl derivatives or its allies in one case. This was in the case of a woman aged thirty-two years, who was admitted with a very extensive eruption in every region of the body. The eruption was much crusted, not very hyperæmic, and I thought it was just a case in which thyroid extract would be beneficial; but in this I was disappointed, for it upset her considerably and made the eruption more hyperæmic and irritable, so that I was obliged to stop it. Two or three weeks later I gave her salophen in fifteen-grain doses three times a day. This was too large a dose, though it was the dose recommended, and it produced diarrhoea and other signs of intestinal irritation. The stomach was given a rest and then a ten-grain dose of the drug was given. Considerable improvement took place, but as she was also having local applications I am unable to say more than that I believe the salophen played a considerable part in the beneficial result of the treatment.

These are by no means all the cases of psoriasis that I have treated in this way, but I will not relate case after case. I will simply state what drawbacks I have found. In the more chronic forms of the disease the improvement has not been so striking, though, except in a few very old patches, there has nearly always been marked improvement. Where progress is slow it is difficult to get out-patients to persevere unless they also have something to apply, and then of course the exact apportionment of the credit to internal and local treatment is difficult. With the single exception I have mentioned, where the dose was excessive and excited intestinal irritation, it has never produced aggravation of the eruption. A few patients, however, were unable to continue salicylate of soda, as it produced dyspepsia in the form of pain in the epigastrium soon after taking it. It was always given after meals to obviate any gastric irritation as far as possible. In one case it actually produced nausea and occasionally vomiting and sweating. The patient was a boy aged thirteen years, who had a moderate amount of eruption, chiefly on the trunk. In spite of this—for I did not stop the drug at once—improvement in the eruption took place, but not to a striking extent. After taking it for a month salicylate of potash in seven-and-a-half grain doses was given, but this disagreed still more; then three grains of salicin three times a day were substituted, and this he was able to take without discomfort, so that the eruption, which was in rings, improved considerably in a fortnight. He is still under treatment. It is possible that the pure natural salicin or salicylate may be more easily tolerated in such patients, but in the great majority of cases the cheaper synthetical product is sufficiently efficacious.

I will only touch briefly upon some other diseases of the skin in which salicylate of soda has been administered with more or less decided benefit. In various forms of erythema multiforme, including erythema iris, I have long used this drug—and, I believe, with advantage—in shortening the course of the eruption; but as so many cases run a short course without any treatment it is difficult to obtain conclusive proof that in any one the short course was due to the drug and not to a spontaneous involution. I would especially suggest its administration in erythema nodosum, a disease which only rarely comes to skin departments at the hospital. In lupus erythematosus, in one case, striking improvement ensued after its administration, which, I believe, was due to the drug. The patient, aged thirty-nine years, had suffered from lupus erythematosus for three years. The patches on the malar eminences and on the bridge of the nose were small and had the usual seborrhœic characters, but he had several large, actively inflammatory patches on the scalp which formed an irregular band of patches distributed posteriorly for about two-thirds of the circumference of the scalp. He was subject to chilblains, but his general health was good and there was no phthisis in the family. I had seen him in March, 1894, and among other remedies he had taken two tabloids of thyroid extract for a

considerable time without any result. I did not see him again until Feb. 14th, 1895, when the patches on the scalp had increased considerably in extent and were very hyperæmic, though I could not say there were new ones. He was given fifteen grains of salicylate of soda three times a day, and locally a mild antiseptic was rubbed gently on to the patches,—viz., four grains of lozoin with one ounce of lanolin and oil. On March 20th all the places were immensely improved. The ears and nose were quite well, and all the scalp patches were very much better. The congestion had almost vanished from most of them, they were becoming cicatricial, and there were only left some sebaceous plugs in some of the patches. Although I believe this improvement must be ascribed to the salicylate of soda, I do not wish to lay much stress on a single case. I have seen a very brilliant cure apparently due to arsenic; but it must be reluctantly admitted that arsenic is of little or no value in the great majority of cases. I have also thought that thyroid extract is occasionally beneficial in lupus erythematosus, and the success of these two drugs, although in exceptional cases, renders it probable that salicylate was the cause of the improvement and suggests that it may at least be tried, the more so as it is less likely to upset the patient than either of its rivals. I have not had time to try it sufficiently in other cases of this form of lupus to enable me to give a more decided opinion as to its merits. In eczema also I have not as yet had any good evidence either for or against it. The irritation is usually so great that local treatment must nearly always be employed, and this complication makes it difficult to appraise the value of internal treatment until it has been used in a large number of cases. I do not expect any great advantage in the majority of cases.

Finally, I would only mention that Arning a few years ago claimed to have had good results in some cases of leprosy from salicylates, but in the few cases in which I have had the opportunity of trying it I have not been able to trace any particular benefit from it; but it might be that it is only useful in the more active cases seen in the tropics, and that in the comparatively quiescent condition of the disease, as it is usually met with, it is less likely to be of benefit. At all events, in the next case with a febrile exacerbation I shall try salicylates instead of quinine, which I have usually employed.

The question which naturally suggests itself is, How does salicylate of soda act beneficially in these various forms of skin disease? In psoriasis, for instance, is its beneficial action a confirmation of the French view of the close relationship of psoriasis and arthritis, whether rheumatic or gouty, or what in our ignorance we call "rheumatoid"? Without denying that these conditions do favour the development of psoriasis, I do not think that the fact that salicylates are beneficial to both acute rheumatism and psoriasis must necessarily be interpreted as a proof of their being more closely connected etiologically than has generally hitherto been suspected; I would rather suggest that the result is due to a microbicidal action of salicylates in the blood—the more so as the evidence accumulates, and has recently been ably marshalled by Dr. Newsholme, that rheumatism is itself a microbic disease—and that the result in both is due to the microbicidal action of the drug. Possibly both microbes find a common factor in the organism which affords a congenial soil. The psoriasis microbe, it is true, is at present hypothetical, and is possibly only one factor in the causation of the eruption, and if it is admitted that it is microbic in origin the clinical facts point to its acting from within the body, and that it is not a microbe simply deposited *ab extra* on the skin. Further, this microbe must have periods of quiescence from which it may be awakened by various conditions of body or mind, chiefly of a depressing character; for Hebra's famous dictum, "that psoriasis is a disease of the healthy," is too often contradicted by clinical facts for it to be accepted as anything more than a paradox to attract the student's attention to the ruddy, clear complexion seen in many young patients suffering from psoriasis.

[Dr. Radcliffe Crocker concluded by asking the members of the society to state their experience as to the indications and contraindications for arsenic and thyroid extract respectively, and as he believed that he was the first to publish good results in the treatment of psoriasis by the internal administration of salicylates summed up his conclusions on these drugs as follows:]

Salicylate of soda and probably salicin and its derivatives are of great value in psoriasis, especially in the period of active development and in hyperæmic cases which are

unsuitable, as a rule, for arsenic and thyroid extract. They are useful in all forms except when they produce dyspepsia, and perhaps in old chronic patches. Finally, they are much less likely to upset the general health of the patient than either arsenic or thyroid extract.

Harley-street, W.

THE TREATMENT OF PSORIASIS.

By TOM ROBINSON, M.D. ST. AND.

How few specifics we can boast of possessing. I suppose if we asked a candidate for a medical examination to name those drugs which we could rely upon to cure a certain malady he would probably say mercury will cure syphilis and quinine will cure ague, and he might possibly say arsenic would cure psoriasis. Can any of us say we possess more knowledge than this hypothetical student? I confess to commencing the study of psoriasis with the most unbounded belief in the power of arsenic to cure my cases; for had I not been saturated with this belief by my reading and teaching? But, alas, when I came face to face with the malady I discovered that my remedy failed most dismally to fulfil my high anticipations, although it was pushed sometimes with all the boldness of Hunt and men of his school. It would be impossible, and it certainly would be wearisome, if any attempt were made to embrace in these few remarks the experience of other drugs in the treatment of psoriasis. Suffice it to say that cantharides, aconite, turpentine, green iodide of mercury, cod-liver oil, phosphorus, and sulphur have been put into the balance and found wanting as specifics for psoriasis. If we wish to ascertain accurately the influence of any treatment we must first obtain the natural history of the disease which we are dealing with. It is very seldom that we are able to do this without some possible error creeping into our considerations, as so few cases of psoriasis come before us which have not been subjected to treatment. On one occasion, however, I have had an opportunity given me for obtaining this desirable information; and so important a bearing had it upon the whole question of treatment that I venture to give it in some detail.

A woman from Lincolnshire aged seventy-six years consulted me in 1891 for chronic gout. On examining her quite a cluster of typical psoriasis spots were to be seen on her knees and elbows. These, she said, had existed since she was thirteen years old, but many times during her life she had been "almost covered" (I give her exact words) with a scaly rash. She was certain that since she had ceased menstruating the eruption had been getting less and less, and she did not think it came out in crops like it used to do. She had had four children, and each time during her pregnancy the rash "nearly left her." During the middle period of her life the eruption was always worse when she was suckling, and it invariably became more exuberant in the spring of the year. She was told when a girl that the eruption "must not be driven in" or it would fasten itself upon some vital organ, and for this reason she never either applied remedies or took any drugs for the disease. If we gather up the facts of this case we shall see they arrange themselves into four headings: (a) the disease commenced at puberty; (b) it has had cycles of rise and fall; (c) it subsided during pregnancy; and (d) it always became more exuberant in the spring. If this woman had been subjected to treatment how impossible it would have been for the most impartial of us not to attribute the improvement which took place to our therapeutic efforts. The practical question is, Can we not subject our psoriasis patients to any treatment with the confident hope that we shall either cure or benefit them? It would be of deep interest if the opinion and experience of a number of those engaged in skin practice would give an answer to this question; for my own part, I should direct my endeavours to—(a) improve the general health of the patient if any error of nutrition or function could be detected; and (b) treat the disease locally. Nothing but experience and what may be called the instinct of the physician will enable anyone to use the first factor. But to remove the scales, and sometimes, I was nearly saying "frequently," to prevent their recurrence, there is nothing which has succeeded so well as a consecutive, efficient, and constant application of equal parts of Stockholm tar, soft soap, and spirit of wine to the psoriatic spots. The remedy must be rubbed in with hot and moist flannel until

the patient can submit no longer, and if the patches are local and large a piece of lint should be saturated with the tincture and tied on for several consecutive hours, even days, if necessary. The treatment must be persevered with until the whole of the morbid material is cast off; and when this occurs we shall find the true skin smooth and shining, looking like gutta-percha tissue, stained as it is with the tar. The misfortune is that this treatment is tedious and objectionable for both nurse and patient, and can only be carried out efficiently in a hospital or medical home, or at least with the assistance of a trained nurse. When the patient has sacrificed three or four weeks to this treatment the general result has been satisfactory, and some cases have, so far as I know, been completely cured; but I doubt whether any measures are capable of preventing a relapse. It is scarcely necessary to add that no claim is raised for originality in the application of soap, spirit, and tar in cases of psoriasis. Hebra, that king of dermatologists, was, so far as I know, the first to use the combination.

A CASE ILLUSTRATING AN EARLY STAGE OF HERNIA OF THE BLADDER.

By FREDERICK TREVES, F.R.C.S. ENG.,
SURGEON TO, AND LECTURER ON SURGERY AT, THE LONDON HOSPITAL.

THE comparative rarity of hernia of the bladder and the little knowledge possessed of the mode of formation of this rupture may excuse the publication of the following case.

A man aged thirty-one came under my care with a double inguinal hernia. He had lived a life of undisturbed leisure, was the reverse of energetic, and took little or no exercise. His whole muscular system was below the average in the matter of development, his tissues were very flabby, and although he was by no means corpulent he had been increasing in weight for some little time. The abdomen was lax and unduly pendulous for a man of his years, and the amount of subcutaneous fat in the parietes was large. He had noticed the hernia for about two years, the left rupture having appeared before the right. A well-fitting double inguinal truss had been worn for the last twelve months. The right hernia was the larger of the two. It formed a swelling which was about the size of a hen's egg as it projected beyond the inguinal ring. It had reached but a little way into the scrotum. It felt soft and was peculiarly rounded. The impulse on coughing was marked, and the protrusion was perfectly reducible. I noticed that while the hernia could be most readily replaced it appeared again the moment the fingers were taken away. The contents appeared to be omental. The ring readily admitted two fingers. The hernia on the left side was very like that on the right. The ring was about the same size, but the protrusion was much smaller. The patient complained of strange, indefinite pains about the lower part of the abdomen. He had no bladder trouble, and his chief complaint was of a constant sense of painful weakness in the groins. He had some pain, moreover, along the inner side of the right thigh. He was very anxious to have both hernia treated by operation. He was much worried by wearing a truss, and expressed his intention of discontinuing the apparatus in any case. It was pointed out to him that the ruptures could be perfectly supported by a truss, and that an operation was not a necessity. He claimed, however, that the truss gave him so much inconvenience that he could not submit to the continued wearing of it. This persistent sense of discomfort in the groin, even when an admirable truss was being worn, was a very noticeable feature. I proceeded to carry out the operation for the radical cure. On exposing the external ring on the right side I found a soft, well-defined, and well-rounded protrusion behind the structures of the cord. It looked like an omental hernia in a very thin sac, but an examination showed that it was in reality a retroperitoneal fatty hernia. When I had removed the fat composing this reducible mass I found in its interior a peritoneal sac about one inch and a half in length as measured by the part drawn out beyond the external ring. This sac, which was quite empty, was ligatured and removed. The removal of this fatty hernia revealed another and larger fatty protrusion behind it. There seemed, indeed, to be two hernia projecting from the inguinal canal, one behind the other, and in front of the anterior of the two was the cord. The removal of the fat

from the second protrusion disclosed in its interior a strange-looking mass which was soon shown to be the bladder. The fat seemed to be adherent to it. When the fat was dragged upon the viscus was drawn out of the ring, while a very little pressure served to reduce it. When reduced I could readily pass a finger into the ante-vesical space. No serous membrane came into view. An examination of the muscular fibres of the exposed bladder made it apparent that the part protruded was the extreme summit. The extruded portion when dragged forward projected (or rather could be made to project) about two inches beyond the external ring. I removed as much fat as possible and closed the external ring with sutures. The hernia on the left side was also a fatty hernia which had come down behind the cord, and which likewise contained in its interior a small empty peritoneal sac. The patient's recovery was uneventful.

Remarks.—This case certainly serves to illustrate the "traction" theory of hernia as held by some. There is an increase in the subperitoneal fat; it grows in a direction of little resistance—viz., along the inguinal canal—and drags a small pouch of peritoneum after it. In the same way the fat in the ante-vesical space extends along the inguinal canal and drags a portion of the bladder after it. Had the fatty hernia extended to the scrotum the hernia of the bladder would have been quite considerable, the protrusion would have been free of any sac, and the viscus would probably have become more or less irreducible. The case certainly shows the part a fatty hernia may play in producing a protrusion of the bladder.

Wimpole-street, W.

ON A SEVERE FORM OF ULCERATIVE COLITIS OCCURRING IN YOUNG CHILDREN IN THE ARGENTINE.

By GEORGE MACKERN, M.D. LOND.,
LATE VISITING PHYSICIAN TO THE BRITISH HOSPITAL, BUENOS AYRES.

As the subject of colitis seems to be attracting some attention just at present, and as an *addendum* to Dr. Hale White's article on "Colitis" which appeared in THE LANCET of March 2nd, I should like to describe a form of severe ulceration of the lower bowel which I have observed as occurring in young children in Buenos Ayres, and which differs very much in its clinical aspects from the usual forms of colitis referred to in that article and in the various textbooks. The form I am about to describe must be carefully distinguished from the other and acute forms of intestinal disease which are commonly observed in semi-tropical climates. The Argentine Republic over its greater extent, and more especially the province of Buenos Ayres, enjoys a semi-tropical or temperate climate, subject, however, to great and sudden changes in temperature. The hot months are January and February, with a mean temperature of 80° to 85° F., with occasional exacerbations to 90°, 95°, or even 100° in the shade, this excessive rise being usually accompanied by a soft north wind blowing from the extensive swamps of the Upper Parana and Matto Grosso districts of Southern Brazil. This north wind produces an extraordinarily depressing and nervous effect on both native and foreign residents. Lassitude, disinclination for bodily and mental exertion, and a peculiar irritability of temper are felt alike by all classes during the two or three days the wind lasts. On such days special precautions must be taken with regard to fresh foods, milk turning sour in a couple of hours, fresh meat beginning to decompose in three or four, while certain fruits rich in sugar will also ferment in a few hours. This great heat culminates in a storm of wind often accompanied by hail, and the temperature drops perhaps 25° or 30° in an hour's time. It is at such times as these that acute and fatal forms of diarrhoea may occur both in adults and in children, in the latter case chiefly due, no doubt, to the ingestion of milk rendered toxic under the influence of the microbe-bearing north wind. Children under two years of age succumb much more rapidly to this form of diarrhoea than older children using a more mixed diet, and adults, though they suffer severely, seldom die from acute attacks. Clinical and pathological observations show that it is the upper part of the intestinal tract which chiefly suffers, and there is often vomiting at the beginning of the attacks, which

are always sudden and violent. The chief symptoms are: 1. Frequent evacuations (the first being often natural and formed) very large, dark in colour, slimy, offensive, and accompanied by great pain and some tenderness over the upper part of the abdomen; towards the end of a fatal case motions become thin and watery though still dark in colour, very frequent, the pain disappears, and there is some tenesmus, due, however, to local irritation of the rectum and anus; the motions are never blood-stained, and mucus is rarely voided alone. 2. High fever, from 103° to 105° being common; no rigors; towards the end the fever drops, except in the very acute cases (under twenty-four hours) when the temperature usually rises to 105° or 106°. 3. Great restlessness and a very anxious expression, very great thirst. 4. Tongue much furred, becoming quickly brown and dry. 5. Abdomen tender in its upper part, but soft and doughy; no tympanitis as a rule. 6. Pulse quick and small from the very commencement. 7. In fatal cases coma precedes death, which occurs from exhaustion. I have given this brief description of acute disease attacking the upper portions of the intestinal tract because it is the only form I have met with which differs from the usual varieties described in textbooks, such as summer diarrhoea, cholera infantum, true or Asiatic cholera, &c.

Returning now to our more immediate subject—ulcerative colitis—the cases I have seen have all been in children under four years of age, the most frequent age being from twelve to twenty months—that is to say, a few months after weaning, and the child out of arms and being able to walk a little; this latter point is important as bearing on the causation. The children of all classes are liable, the differences in nutrition between the richer and poorer classes in Buenos Ayres not being so marked as in the more crowded populations of the larger European capitals. Most cases occur in the early winter (June and July), more especially if cold and wet come together rather suddenly, and this offers the only clue towards the discovery of the etiology of this remarkable disease. Most of the houses in the city possess large open courtyards (*patios*) and often small gardens, and the children live to a great extent an open-air life, and on the advent of the cold and damp winter are allowed to run about perhaps too freely, and so from sitting down on the damp grass or on the marble steps may catch cold, and the lower bowel become affected directly. Casting about for a cause, this seems to me to be the only likely one.

I shall now give the description of a severe and typical case which occurred in my own practice. An infant aged fifteen months, male, of English parentage, no previous illness, strong and well nourished, though somewhat backward in teething, had been weaned at ten months, the mother rather overtaxing her strength in nursing so as to bring him well over the hot weather before beginning the new diet, which consisted chiefly of groats prepared with milk, prepared food, cracknels, and well-made beef-tea once or twice a day, with an egg occasionally. The child thrived, and at the time of his illness (July) was allowed to run about the *patios* and garden, although the weather had turned somewhat cold and damp. On a Thursday night he suddenly awoke with a croupy cough, and when I saw him he was flushed with a temperature of 100.5° F. and had a short brassy cough, the pharynx being normal in appearance. I treated him with drop doses of tincture of aconite, minute doses of Dover's powder, and hot turpentine stupes to the neck. Next day the croupy symptoms had passed off, the temperature was down to 99°, and the bowels were fairly moved after small doses of calomel. On the Friday night he had very slight return of croupy symptoms, and on Saturday morning he appeared to be well. But in the afternoon he began to pass clear mucus from the bowel without any pain or straining, and during the next two or three days mucous discharges alternated with fairly normal motions every six or eight hours, and there was very little, if any, constitutional disturbance, the temperature varying from 99° to 100°, the tongue fairly clean, the appetite good, and but little restlessness at night. During the fourth and fifth days the mucous discharges became more abundant, some of them being distinctly pink in colour; the motions were infrequent, but very large, rather slimy, and slightly offensive. On the seventh day he began to pass the masses of mucus characteristic of the disease, some being about the size and shape of a cricket ball, and of a peculiarly dark red colour like port-wine jelly; there would be perhaps not more than two or three of these masses in the twenty-four hours, and in between these would be a fairly good motion,

though loose and slimy; the appetite failed somewhat, and the tongue was only slightly furred; sleep was rarely interrupted, and there was absolutely no pain or tenesmus on defecation; but the temperature went up to 102°. On the eighth and ninth days the masses of mucus were mixed with membranous shreds and sloughs decidedly fetid, and the motions became looser, flaky and curdy, and horribly offensive. On the tenth day in the afternoon the temperature suddenly went up to 105° and the pulse to 130, and the child for the first time threatened to become collapsed. I gave him a warm bath rapidly cooled down with ice, and the temperature came down to 102°, and he became bright again; he continued taking food well and enjoying very fair sleep. During the next few days he passed the masses of mucus mixed with shreds of sloughy membrane, and on several occasions black gangrenous masses horribly fetid. Small quantities, never exceeding a teaspoonful, of bright red blood usually followed the gangrenous sloughs, evidently coming from the edges of the ulcerated patch. After a particularly good sweeping of the surface of the ulcer (for so it seemed to me) there would follow two or three slimy offensive motions not showing a trace of membrane or slough. By this time the child had become somewhat emaciated and pale, but his general appearance was no index of his grave condition. For some days he remained more or less in the same state, passing mucus, sloughs, and bright blood, though in less quantity, and the motions were large, loose, and foul, but not so frequent as to exhaust the little patient alarmingly, and during this trying time he rarely refused his food, slept fairly well, and was with difficulty kept in bed during the day; the temperature never rose again. The symptoms gradually improved, the discharge of blood ceased entirely, sloughy-looking masses were passed at longer intervals, and the motions improved in consistence and appearance, and about five weeks after commencement of the illness he was able to be moved to the suburbs. Convalescence was slow and vexatious; the bowels were irregular, with occasional mucous discharges and fetid motions, and, strange to say, the appetite became capricious and poor; the attractions of a large garden and fine weather were trying to him, and he was liable to overtax his strength in getting about. Ten months afterwards he was brought to England, where he now is perfectly well and strong; but on the voyage he had a short but mild relapse, with mucous discharges and fetid motions.

I confess I did not at first recognise the gravity of the case, the absence of fever, constitutional disturbance, and tenesmus dispelling all fear of dysentery. But on the appearance of the first masses of blood-dyed mucus and the rise of temperature I sought the aid of Dr. Ricardo Gutierrez, senior physician to the Children's Hospital, who, in view of the immense quantities of blood and mucus that were being passed, and especially in the presence of sloughs, gave a very serious prognosis. For the first day or two we gave a castor-oil emulsion, one teaspoonful every two hours, with two or three grains of powdered salol every four hours as an intestinal disinfectant, the object being to keep the bowels fairly loose and so prevent any damage to the ulcerated surface, and also to remove intestinal accumulations as quickly as possible and to hinder stasis. This we followed up with calomel in frequent minute doses (one-fifth of a grain), combined with opium (one-third of a grain) and salol (one grain). By these means we kept the intestinal circulation going well, and perhaps avoided retention and absorption of toxic material. Later, when the discharge became alarmingly abundant and the large ulcerating surface apparently increasing, recourse was had to astringents, both vegetable and mineral, but they failed to make much impression, the best being hæmatoxylin mixture, which, however, was often passed unchanged. At the worst and gangrenous stage we tried rectal injections of all known astringents, including raw and clear starch and opium, extract of rhatany, extract of hamamelis, tannic acid, alum, iron, turpentine, nitrate of silver, permanganate of potash, carbolic acid, &c., with but little appreciable effect, the best perhaps being liquor ferri perchloridi, twenty or thirty drops per ounce of water. Small injections only were used, not exceeding 3 oz. of liquid, for fear of dilating the diseased and thinned-out colon. In subsequent relapses I gave the calomel, opium, and salol powders, the hæmatoxylin mixture, and the nitrate of silver or iron injections. But in future cases, so soon as the diagnosis is established, I mean to use enterocolysis to its fullest extent, giving rectal injections, with the long tube, of

astringent and antiseptic solutions, not less than a pint or a pint and a half at each injection. This treatment is much recommended by the Italian school, but it is obviously only applicable in the earlier stages. A properly regulated diet is exceedingly important, the indications being to give a bland, nutritious, non-irritating food, easily absorbed and grateful to the patient, who has to fight it out but poorly aided by drugs. But when curdy, fermenting masses appear in the motions the diet must be varied, and we used with great advantage fresh and rather weak beef-tea, fresh veal broth, and calves' feet jelly; and, when all these were refused, raw meat, prepared by finely scraping good fresh mutton, mixed with quince jelly, was well taken and well digested. In convalescence prepared food twice a day and underdone mutton or beef are the best, with small quantities of the best old port wine you can get. Rice water, linseed water, weak tea, and slightly acid drinks may be given to relieve thirst.

From the foregoing description it will be seen that this disease differs very considerably in its clinical symptoms from dysentery and ordinary colitis and so-called "mucous disease." In the first place, the large masses of mucus are peculiar—they are "blood-dyed," if I may use the expression, just like lumps of dark wine-jelly, and at first contain no liquid blood or even small clots; they are voided easily, without straining; there is no pain, either preceding evacuation or after, and fairly good motions at first follow these masses. Later, the motions become slimy and blood-stained, or accompanied by small clots of a bright-red colour, which may be seen on the top of the motion if the child has used the chamber. In the later stages and in the worst cases sloughy masses and black, gangrenous shreds, smelling horribly, may be passed. From the increasing size of the masses of mucus in the above case, their compactness and their shape, we could easily deduce that the ulceration was more or less circular in shape, that it advanced by the circumference, that the older portions first sloughed and then became gangrenous, and that at one time the ulcerated patch must have measured at least six or seven inches in circumference. The pathological sequence of events was apparently as follows: (a) catarrhal inflammation of the mucous coat just above the sigmoid flexure of the colon; (b) increasing hyperæmia and venous vascularity giving rise to wine-coloured mucous discharges; (c) breaking down of the surface of the mucous membrane with formation of sloughs, and a process of auto-infection due to development of toxic inflammatory products; (d) gangrene and extension of ulceration along the edges; (e) constitutional disturbance due to absorption of morbid products; (f) limitation of infective process and further ulceration by the formation of a protection zone in the lymphatic system just below the muscular coat; and (g) healing of ulcer from the circumference to the centre. The perusal of the clinical history of the case will clearly prove this series of pathological changes; in fact, as Dr. Gutiérrez put it to me, the diagnosis, course, and even treatment of these cases can be made out by mere inspection of the napkins and dejecta alone. What connexion there was between the laryngeal catarrh of the preceding two days and the intestinal attack I am not prepared to state. In another of my cases a similar sequence took place; but Dr. Gutiérrez assures me he has not observed the complication, if complication it really be. Another very interesting point in this case was the comparative ease with which nutrition was kept up, differing in this respect so widely from dysentery, the explanation being that the ulcer, large as it was, was situated at the extreme end of the alimentary tract; secondly, that blood infection and constitutional disturbance were comparatively slight in proportion to the large local lesion; and, thirdly, the child was kept as much as possible to his usual regime, being encouraged to take his food and to sleep at his accustomed hours. Ultimate and complete recovery is usually retarded for two or even three years, nutrition being but slowly carried on. In my case, in spite of considerable emaciation and wasting of legs, buttocks, and upper extremities, recovery was complete within the year, and due, I think, to very efficient nursing and a very great care in the preparation of the food during the acute stage. Another important point is that, according to Dr. Gutiérrez, cloacal contraction of the lumen of the bowel never follows, and in my case—one of the worst he had ever seen—the child is now (eighteen months after illness) having motions of proper shape and size. In all these points the natural history of the disease differs

widely from dysentery, with which the earlier symptoms may be confounded, and as a remarkable instance of extensive local intestinal ulceration with recovery I have ventured to put the case on record *in extenso*.

Buenos Ayres.

TWO CASES OF FÆCAL FISTULA TREATED BY RESECTION OF BOWEL.

By HERBERT W. PAGE, F.R.C.S. ENG.,

SURGEON TO ST. MARY'S HOSPITAL.

IN THE LANCET of Jan. 13th, 1894, I recorded two cases of resection of small intestine, gangrenous in hernia, one of which was primary and fatal, the other secondary and successful. The notes of two more recent cases of secondary resection—one of large bowel which had been ruptured by injury and was followed by fæcal fistula, and the other of small gut which had in all probability been gangrenous in a femoral hernia, and was likewise followed by fistula—both of them successfully undertaken, may be thought to be of some interest and worthy of publication.

CASE 1.—A man aged twenty-seven years was admitted to St. Mary's Hospital on Oct. 21st, 1893, having been run over a few minutes before by the trap which he had been driving and from which he had been thrown. He believed that a wheel had passed over the lower part of his back, and here there was a decided linear bruise. He complained of pain below and to the outer side of the left anterior superior iliac spine, and at this place there were slight redness and swelling. There was no marked collapse, nor did he seem very ill, but it was thought right to keep him in the hospital and in bed. There were, so far, no evidences of internal injury, but the man was restless and uncomfortable; and on the 28th—that is, a week after his accident—his evening temperature rose for the first time to 100° F. Coincidentally with the fever he made greater complaint of pain in the left loin and ilio-inguinal region, and this steadily increased day by day. His temperature, moreover, rose to 101°. Presently there was a suspicion of fulness and increased resistance in the left flank, the part became tender, and on Nov. 11th—the temperature on the previous evening having been 102°—there was distinct fluctuation between the left great trochanter and the crest of the ilium. From this spot fæcal pus was evacuated by incision, and soon afterwards solid fæces came from the opening. Two days later it became necessary to make a second incision immediately internal to the anterior iliac spine, and from this also there was a copious fæcal discharge. The first wound below the iliac crest closed soon after the more internal and direct route had been established for the discharge. The character of the fæces pointed clearly to their escape from the large bowel, but it was impossible to say with certainty whether the perforation had been the immediate result of the injury or had followed the sloughing of a severe contusion. The history of the case rather inclined us to regard the second cause as the more probable. At any rate, the fæcal escape was altogether extra-peritoneal, and we determined to see what rest, drainage, and cleanliness might do towards closure of the fistula before hurriedly resorting to operation. Although from time to time it looked as if the hole were going to close, the hopes of it were blasted by renewed discharge, and on Jan. 20th, 1894, three months having passed since the accident, and the discharge of fæces being as great as ever, it was resolved to expose the gut, and, if the orifice were a small one, to endeavour to close it by infolding of the wall with lateral sutures. Free incisions were required in order to find the bowel. It was firmly bound by adhesions, but by carefully following the route of the fistula that part of the bowel which was perforated was found without disturbing the whole circumference of it. In this way the general peritoneal cavity was avoided. A longitudinal rent with jagged edges, three-quarters of an inch in length, was found at the lowermost end of the descending colon and, as far as could be judged in the confusion of adhesions, at that side of it which is commonly uncovered by the peritoneum. A sufficient length of bowel having been freed to make the manipulations easy, lateral Lembert sutures were inserted so as to infold the wall of the gut and hide the rent, in the hope that peritoneal adhesions might be formed

of sufficient strength to close the opening. The depths of the wound were packed with iodoform gauze. The man, who had been extremely nervous beforehand and had with difficulty consented to the operation at all, bore it badly and was very sick after it. The next day his abdomen was a good deal distended, and the distension had increased so much by the third day that I felt sure no sutures could possibly hold, and when the wound was dressed on the 23rd we were not surprised to find that there had been much escape of feces. The explanation of this great accumulation of flatus lay in the fact that he had been continually gulping and swallowing air, a habit of which it was obviously imperative to cure him before undertaking any further operation. In the meantime, however, he was wishful that another chance should be given to spontaneous closure, and it was therefore not until March 10th that, the fistula being as bad as ever, resort was had to resection of the damaged piece of bowel. On this occasion it was necessary to open the peritoneum by a vertical incision three inches in length external to the linea semilunaris, and, having joined this by a second at right angles which included the fistulous track, the piece of damaged gut was found adherent to the pelvic and neighbouring abdominal wall. By careful dissection it was ultimately separated, and a couple of inches were then removed. The ends were united by the Czerny-Lembert suture. The abdominal wound was closed by tiers of sutures, save in that part where the external opening of the former fistula was, and here the depths were plugged with iodoform gauze. The after-history was uneventful, but on the 12th and two following days the dressings were fecal in odour, and there was certainly escape of flatus if not of solid feces. The opening, however, must have been very small, for by the 21st there was no longer any suspicion even that the ends of the gut were not soundly united; and on the 25th the patient had his first natural action of the bowels. Thereafter all went well, the abdominal wound healed in due course, and he was discharged on May 4th. When seen a few months afterwards he was in all respects perfectly well.

Although more than six months were spent over the treatment of this case it is questionable whether a better result would have been attained had resort been had to resection at a much earlier time. Apart altogether from the man's aversion from operation, it would in all probability have been a more dangerous thing to have opened the abdomen when the surrounding parts were in a state of acute inflammation from the spread of fecal contamination, and it was doubtless better to wait until the route for the fecal discharge had settled down into the comparative quietude of a distinct sinus. The ultimate result in this respect justified the delay. How far the failure of the earlier operation in January was due to faulty methods or to the impossibility of closing the rent—or, indeed, any rent—by the method adopted it is impossible to say, but I had no doubt at the time that the enormous distension of the gut with air had much to do with the yielding of the sutures and the early escape of feces.

CASE 2.—A woman aged forty-two years was admitted on Nov. 15th, 1893, with a fecal fistula at the upper part of the right thigh. The position of the opening was immediately below Poupart's ligament, external to the pubic spine, and suggested perforation of gut from gangrenous hernia. This diagnosis was supported by her history, for she said she had had a violent attack of pain a year before at this site, with the development of a lump which gradually increased in size. After the lapse of six months she became much worse, was laid up at home with inflammation, and then the lump burst. There had been discharge of feces ever since, now from one point and now from another, fresh abscesses having formed and burst from time to time. One fistula alone was present on her admission, but there were the scars of former orifices. She suffered a good deal of pain. The patient absolutely declined to submit to operation, and attempts were made to close the sinus by injections of nitrate of silver. They had no influence, and, still declining operation, she left the hospital on Dec. 7th. She returned on March 31st, 1894, converted by the inconvenience and suffering to the necessity of operation, and this was accordingly undertaken on April 11th. A vertical incision, which had to be extended through Poupart's ligament, was made over the site of the fistula, and it was soon found that a small area of the circumference of a piece of ileum, with an orifice in the centre, was adherent to the tissues of and adjoining the upper end of the crural canal. Part only of the lumen of the gut was

thus adherent, and everything pointed to gangrene of a hernia of Richter's variety. There was no difficulty in isolating the implicated portion of the bowel, and, three inches having been removed by slightly diagonal section, the ends were joined by the Czerny-Lembert method of suture. The whole of the abdominal wound and the major part of that in the thigh were closed by sutures, but the exact site of the fistula was plugged with gauze. The woman bore the operation extremely well, the wound healed forthwith, and she had her first natural action of the bowels on the 20th. Her general health rapidly improved afterwards, and when seen in April of the present year she was well and having a daily natural action without pain or difficulty.

This case was a good example of one of the results of gangrene from the neglect of a hernia which has not been recognised and submitted to treatment. In all probability the general symptoms were never very grave, and had the woman come under observation at the time the case would have been especially suitable for primary resection, and the use of some artificial method for the rapid approximation of the divided ends of the bowel. Of the various instruments for this purpose there can be no question, I think, that Murphy's button has in the main been followed by the best results, and is the one most free from danger. My thanks are due to my dressers, Mr. Tenison, Mr. Herrington, and Mr. Austin, for their careful notes and the interest they took in the treatment of these two patients.

CASES ILLUSTRATING THE SURGERY OF THE KIDNEY.

By J. KNOWSLEY THORNTON, M.B., C.M. EDIN.,
CONSULTING SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN
AND CHILDREN, AND TO THE NEW HOSPITAL FOR WOMEN, AND
THE GROSVENOR HOSPITAL FOR WOMEN.

(Continued from p. 865.)

THE present communication brings my cases of abdominal nephrectomy up to date, and I am sorry to say that two of the cases were fatal, though one of them was so on account of an unfortunate complication not properly to be referred to the operation itself.

CASE 47.—A young woman aged thirty-two years was first seen in the spring of 1894 on her return from wintering abroad for her health which had long been unsatisfactory. She had for many years suffered very frequently with most severe spasmodic asthma, and her menstruation had never been properly established, there being only an occasional slight pale discharge hardly to be considered. When I first saw her emaciation was extreme; I hardly ever saw anyone so thin, and yet she was bright and full of "go," and would join in the social pleasures of her position. On examining the abdomen, in which she said she had a painful swelling, I found a large, tender, and very mobile kidney, and at this visit I thought it might be merely a floating kidney distended with urine. Subsequent examinations, and the use of the thermometer, soon convinced me that the condition was much more serious, and that she was suffering from advanced tubercle of the kidney, and I asked Sir William Broadbent to see her with me. He had already seen her some years before, and had then found the urine normal. He agreed with me as to diagnosis, but thought there was no immediate urgency, and that the nephrectomy which I had suggested might be deferred and the patient watched for a time. Soon after our consultation she became so much worse that I was obliged to confine her to bed. The pain became very severe; the evening temperatures ran high—from 102° to 104° F.; sweating was profuse; and the kidney became fixed, so that I feared some perirenal infection had occurred. The patient herself was very averse to operation, and much valuable time was lost before I could obtain her consent, her general condition through these weeks becoming daily more serious and more unfavourable for a severe operation, while the local condition led me more and more to fear perirenal complications, such as I have described in previous cases as most seriously affecting the immediate results of operation. In July Dr. Douglas Powell kindly saw her with me, pronounced the lungs to be sound, and joined me in urging the necessity for operation; at last she consented, and I operated on July 24th. The kidney was a

mere thin-walled sac full of pus and cheesy debris; enucleation was very difficult, and some fouling of the tissues of the capsule was unavoidable, but the peritoneum was kept entirely free from any contamination, and whenever I was conscious of any escape the parts were at once cleansed with a 1 in 1000 corrosive sublimate solution, and the whole sac was carefully washed out with the same solution as soon as the kidney was out. Some idea of the difficulties of the enucleation may be gained from the fact that the operation lasted two hours and a half, the greater part of the time being spent in separating the kidney from its upper and posterior attachments, where the adhesions were remarkably dense. The sac was drained with a glass tube in front, very little bloody serum being obtained, and from first to last there was not the least suspicion of odour about the discharge—indeed, its scantiness was sufficient proof that it was aseptic. The patient began to vomit spasmodically and violently immediately she recovered from the effects of the chloroform, and continued to do so till she died rather more than forty-eight hours after the operation, severe hiccough being also troublesome during the last twenty-four hours. The temperature was practically normal till the ante-mortem rise, and the remaining kidney acted well in spite of the small amount of fluid retained in the stomach. There can be no doubt that this patient's condition was most unfavourable for so serious an operation; but the result disappointed me, and I believe that she would have made a good recovery had it not been for this sickness, which seemed to partake of the spasmodic nature of her asthma and was quite unlike the sickness following anaesthesia. Before the operation she was very much depressed and quite made up her mind that it would kill her, a condition most unfavourable for recovery; but after it was over she was quite hopeful in spite of the sickness, and was greatly disappointed when I told her shortly before death that I feared she was dying, remarking, "Oh, I thought I was doing quite well if I could only get over this sickness." The lesson to be learned from the case is to avoid all unnecessary delay when once it becomes evident that operation offers the only hope of cure. The young woman (*vide* Case 23 in my table) upon whom I operated in 1888—sorely against my own will, because I considered the case hopeless—is married and pregnant, and the condition was worse than in the case just recorded, but the one patient was determined to get well and the other was certain she should die.

CASE 48.—The patient, a young woman about thirty years of age, was never very strong, and her family history was not a good one. I had operated twice upon one of her sisters for renal calculus. She herself had suffered from pain in the left renal region ever since she could remember anything, but I only saw her first for it in 1894, and then found a large and very mobile kidney, and advised a belt and pad, which gave temporary relief, but later in the year the kidney became so large and painful that I advised its removal. The operation was performed on Oct. 15th, 1894, and was perfectly simple so far as the kidney was concerned, and I could find no cause for the hydronephrosis except the mobility. I found a small tumour of the right ovary and removed it at the same time—a matter of some little difficulty—through a left lateral incision. She made an excellent recovery from the double operation, and has since been in better health than she had been for some long time previously.

CASE 49.—This case was a very disappointing and very sad one, because I believe the fatal result was due to a chain of circumstances entirely outside my control. The patient was a married woman aged thirty-seven; her first child was born in 1881 and she made a smooth recovery, but in two subsequent confinements in England, in 1883 and 1884, the convalescence was slow and there was much swelling of the legs. The same occurred when she was confined of triplets two years later. In 1891 Dr. Pye-Smith diagnosed misplaced kidney, but advised against operation. In 1893 she was again pregnant, but had such severe attacks of pain, with loss of consciousness and slight convulsions, that abortion was induced. She came to me in December, 1894, and I found a much enlarged mobile right kidney, markedly tender all over. I recommended its removal, and she came up to town immediately. I returned from my Christmas holiday in January. The weather was bitterly cold; she had only recently returned from India, had been taken great care of before coming up to town, came

up in a well-warmed railway carriage, and then drove in a hansom cab to a nursing home. She felt that she had got a chill, but never said a word to me and let me proceed with the operation next day. The operation was a perfectly simple one. The patient was very slow in going under the chloroform and very dusky-looking while under, but came out quickly and well. Very soon afterwards she began to complain of her throat, and then told me about the chill and that she was subject to laryngitis on slight provocation. The operation was performed in 1895, and the mischief spread from the throat into both lungs; on the third day the pulse, which had remained quiet and good up to this time, suddenly became quick and weak, and there were severe attacks of cardiac pain. She died early on the morning of the fourth day, evidently from the double pneumonia. There was never any symptom from first to last to suggest any trouble in connexion with the operation, and the kidney acted well till she was in a dying condition, thirty-three ounces and a half of good urine, with copious deposit of urates, being passed the day before she died. I could not in any way blame myself for this unfortunate result, as it was not till after the operation that I was told anything about it, and I had taken every possible care. One naturally reviews more closely all one's proceedings in an unfortunate case of this kind, and I could not help wondering whether the result would have been different had I contented myself with fixing the kidney into the loin. My rule is never to remove a floating kidney simply because it is a floating kidney, but if it is also hydronephrotic then I remove it as I do any other kidney in which there is decided hydronephrosis, because I believe nothing but removal is of any use. This case was just on the border line, and I could not help feeling, when "wise after the event," that had I decided in favour of the less serious operation the exposure would have been much less than in opening the abdomen, and the condition of the patient with two kidneys in place of one better for fighting through the serious illness which followed. The danger in fixing a loose kidney which has become hydronephrotic is that the ureter, having been already stretched and altered, may be too long when the kidney is fixed in its natural position, and then more or less kink will become permanent and the patient be in a worse condition than before. I have seen this condition produced in a case not hydronephrotic, in which the mobile kidney was fixed too low, the result being that the ureter was always more or less bent on itself, and the pain, which before had been occasional, became constant, because the pelvis of the kidney was always more or less distended with urine.

Having completed the record of my experience in abdominal nephrectomy, I propose very briefly to record the results I have obtained in fixing the loose kidney by sutures into its proper place in the loin—i.e., nephrorrhaphy. The first time I performed this operation was on May 12th, 1886, at the Samaritan Hospital, and I cannot say with what success, as I have entirely lost sight of the patient; but I think it is probable that the result was not perfect, as, having at that time neither experience of my own nor the record of that of others to guide me, I performed it in what I should now consider to be an imperfect manner. The patient was a young woman aged nineteen. She was placed under my care by my colleague Dr. Amund Routh. I merely exposed the kidney in the loin, and attached it by four fine silk sutures to the capsule, cellular tissue, and muscle in the incision, passing the sutures for about half an inch under the true capsule of the kidney. The second case was also sent to me by Dr. A. Routh. The patient was aged twenty-six and had begun to suffer from dragging in the right side and pain in the right groin in 1885; then a lump appeared which she could move about, and in March, 1886, just a few weeks before my first case, she had the kidney sutured into its place by a well-known surgeon who has devoted special attention to renal surgery. The dragging sensation was relieved for about a year, but the pain in the groin was rather worse; at the end of the year the mobile lump in the side reappeared, and very soon the dragging sensation also returned. I determined in this case to open the abdomen and see exactly what the condition of things was. I operated on July 2nd, 1890, and found that the kidney was twisted, so that its lower end pointed forwards, and it was evidently still held in this position by the adhesions formed after the previous operation. I freed it, and, holding it in proper position, passed

two strong sutures through an incision in the loin, carrying them more deeply into the kidney substance than I had done in the previous case, and bringing them out through the loin tissues, except the skin, one at each edge of the loin wound, which I left gaping open without sutures and dressed from the bottom with gauze. The result in this case was satisfactory, and the patient was able to do her work quite well. I last saw her about a year ago. I did not again perform the operation till January, 1893, when I operated upon a woman whom I saw in consultation with Dr. MacLagan. In this case I adopted the method which I have since followed, making a longitudinal incision from an inch and a half to two inches long well through the true capsule of the kidney, whereupon the wound gapes, and I then pass four sutures, one at each side and one at each angle, well into the substance of the kidney, and then through all the tissues of the loin wound at its upper and lower angles and in each side, as in the renal wound, and tie them externally, including a small edge of the skin. I then put in a rubber drainage-tube up to the kidney, and carefully suture the loin wound round it. I arrived at this method of operating from a study of the literature of the subject and a consideration of the importance of involving in the newly formed adhesions some tissue less yielding than the loose cellular tissue and fat around the kidney. The true fibrous capsule is an excellent material, and its cut edge curls back and comes into close union with the other cut fibrous tissues in the loin wound when the sutures are tied. Since adopting this plan I have had uniformly satisfactory results. I always clip away all the loose fat and cellular tissue which is pulled into the wound in exposing the true capsule of the kidney, as I think the contraction which results from its cicatrization aids in retaining the kidney in its place. I have only performed the operation eight times altogether, but my results since adopting the above method have been so encouraging that I have no hesitation in recommending it in any case in which the kidney is not only mobile but is a cause of inconvenience or of suffering. I have no doubt that undue mobility of the kidney is much more common than is supposed, and that it is a cause of many obscure pains and nervous conditions which are put down to fancy or hysteria.

(To be continued.)

THEORETICAL AND PRACTICAL CONSIDERATIONS ON WHOOPING-COUGH,

WITH AN INQUIRY INTO THE THERAPEUTICAL VALUE OF COCAINE IN UPWARDS OF 300 CASES.

REGISTRAR AND ANÆSTHETIST TO THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN.

THERE are many features in the history of whooping-cough, such as its fairly definite incubation period, its infectiousness, and the immunity conferred by one attack, suggesting a microbial origin, and various specific parasites have been described by Poulet,¹ Letzerich,² Ischmer de Gratz,³ Burger,⁴ Moncorvo,⁵ Afanassiew,⁶ and Ritter;⁷ but we are not at present in a position to state that any bacillus has definitely been proved to be the cause of the disease. Other investigators regard whooping-cough as purely a neurosis, and a few cases have been recorded where the post-mortem appearances

seem to lend support to this view. The late Dr. Sturges⁸ was a strong supporter of the primary nervous nature of pertussis. On analysing the clinical history of a large number of cases spread over a considerable period of time the fact that the disease is very infectious becomes remarkably obvious, and the frequency of incidence shows curves similar to those for other infectious diseases.⁹ After infection there is an incubation period of about twelve days, then the temperature rises, the child becomes peevish, there are inflamed conjunctivæ, running at the nose, sneezing, and the symptoms of bronchial catarrh. These persist for a varying length of time, averaging perhaps a fortnight or less. Cases may occur in families of which other members have well-marked pertussis that show the symptoms, but never have the spasmodic whoop. In a typical case after or gradually developing out of the catarrhal stage there arises the paroxysmal stage when the whooping inspirations occur that give the disease its name. There may be other signs of vagal excitability, such as sudden and frequent vomiting, during the paroxysms even momentary stoppage of the heart's action (Steffen), the child may faint, and Lerve symptoms, such as twitching of the muscles of the face, convulsions, and strabismus, occur, while ascending paralysis has been observed in a few cases to follow whooping-cough. Constipation is frequent. Such symptoms as ecchymoses, turgid veins, or cerebral hæmorrhages, which are probably produced by the mechanical strain of the paroxysms, do not concern our present purpose; but the well-known fact may be mentioned that at the end of the attacks a little mucus is usually expectorated. It is very remarkable that with the onset of the violent whoopings the temperature, elevated in the catarrhal stage, becomes normal, the appetite may be good even when there is vomiting, the peevishness disappears, and, except for the paroxysms, the child appears quite well; but in a large number of cases slight causes, such as the taking of food, produce whooping, which is followed by vomiting, or there may be frequent vomiting without preceding paroxysms. The child, finding from experience that food often produces the distressing attack, refuses it, and consequently becomes emaciated, while the loss of sleep due to the exacerbations of cough at night tends in the same direction. When rises of temperature occur in this stage they are almost always due to concomitant broncho-pneumonia.

It seems to us that the disease may be explained on the assumption that it is due to some microbe (whether this be the particular bacillus described by Afanassiew or not is immaterial) which has a local habitat in the respiratory mucous membranes, and by its presence and the products of its activity produces the catarrhal stage of the disease just as the diphtheria bacillus produces membrane locally and general pyrexia. We believe the pertussis microbe also fabricates some virus, which taken into the circulation acts as an irritant poison to the nervous tissues, especially the respiratory and vagal centres, rendering them far more easily excitable than normal. We therefore regard the catarrhal stage as the period of microbial activity and the whooping one as due to the after-effects of a poison generated by the microbe. This affords, if true, a complete reconciliation between the bacillary and neurotic theories of the disease. We are not at present in a position to give experimental proofs, but think the following clinical facts point strongly in favour of our theory. The onset, infectious nature, and subsequent immunity are quite similar to those of diseases commonly accepted as due to microbes, while the absence of pyrexia and often improved general condition of the patient during the whooping stage, its chronic and variable course, the fact that lesions have been found post mortem implicating the medulla, brain, and vagi,¹⁰ and that the whooping when once fully established becomes chronic, tending to slow and sure recovery, not to increased violence, together with the observation that remote nerve lesions are occasional sequelæ, all seem to point to the effects of chemical traumatism of nerve tissues rather than to the presence of active bacilli. The strong resemblance in some respects to the clinical history of post-diphtheritic paralysis seems to show that it is possible a somewhat similar condition obtains to that which Martin has shown occurs in diphtheria. It may be objected that in diphtheria subsequent paralysis

is only an occasional result, while in pertussis this view demands that the nerve poisoning should be constant. It is quite possible that such is actually the case, but one must remember that the catarrhal stage of whooping-cough is unrecognisable from many cases of simple cold, and perhaps the disease without the subsequent paroxysms is far more common than we at present have any idea of; indeed, according to Goodhart pertussis in very young children is often not attended by any whoop. Another possible difficulty is that in diphtheria a paralysing lesion occurs, while here an irritating one is suggested; we do not, however, consider the conditions identical, but only analogous. It may also be objected that, given the presence of irritating bacilli in the respiratory mucous membrane, there is no necessity to invoke the aid of any nerve poisoning in explanation of the symptoms; but we fail to see how the vomiting, which is often quite out of proportion to the whooping, the stopping or slowing of the heart's action, the constipation, the facial convulsions, strabismus, &c., can be explained on the simple presence of an irritant in the respiratory tract, or why the disease should show two such different stages, for if the presence of the microbes were the sole cause why do the pyrexia and first constitutional symptoms not continue during the paroxysmal stage? The fact that the whooping is often started by draughts, irritating vapours, and especially by taking food is exactly what would be expected on the assumption of an increased excitability of the respiratory and vagal centres, while the observation that children not suffering from pertussis sometimes whoop quite fits in with the above view, for what is claimed is a hyperæsthetic condition of part of the medullary centres comparable to the condition of the spinal cord in strychnine poisoning. Probably in some cases the microbes may exist in the respiratory tract for a long period after the catarrhal stage has passed off in the same way that Löffler's bacilli may be present in the throat of a diphtheria patient some weeks after the clinical signs have disappeared; and this supposition would account for those cases which apparently suffer relapses from chills during recovery. The mucus that is expectorated after an attack of whooping is probably due to the congestion of the lungs produced during the paroxysm; very likely each attack, by congestion, secretion of mucus, and other mechanical effects, helps to prepare causes of irritation which give rise to the next by acting on afferent nerves going to the too easily excited centre. In this connexion it may be mentioned that we consider the congestion and mechanical injury done to pulmonary tissue by the spasms of whooping, together with the debilitated state of the child from vomiting, as the chief causes of broncho-pneumonia and other pulmonary diseases in these cases, rather than any subtle influence of the specific cause of pertussis. After examining a large number of cases, and consulting a copious literature on the disease, we do not know of any symptoms which may not be explained on the above hypothesis or as the mechanical effects of the paroxysm.

Treatment.—If the views we have stated be correct the best method of treatment would obviously be by some agent which should destroy the microbe and counteract the effects of its poison. Such a drug is unknown and would have to be applied early in the catarrhal stage, when cases, as a rule, are not seen and cannot be diagnosed with certainty, so we must look for some drug which will antagonise the effects of the poison. It should have a paralysing action on the vagal (vomiting) and respiratory centres, or should stimulate nerves antagonistic in action to those involved, and should, if possible, lessen the sensibility of the peripheral terminations of the afferent nerves from the respiratory and gastric mucous membranes to the medulla. If it hinder the secretion of mucus so much the better. We have a drug which will do all these things in cocaine. This agent has been recommended by many writers as a local application in whooping-cough. Moncorvo¹¹ in a series of papers recommended the application of resorcin to the mucous membrane of the pharynx, the parts having first been rendered insensitive by hydrochlorate of cocaine. Barlow,¹² pursuing the same line of treatment, obtained satisfactory results in fifty cases. Holt,¹³ using 4 per cent. solutions of hydrochlorate of cocaine in five cases of children aged three months, four months, six months, eight months, and twenty-one months old respectively, and after that resorcin, obtained toxic symptoms in all, the chief being restlessness, convulsive movements,

dilated pupils not responding to light, rapid pulse, and delirium. These results are certainly exceptional, though the dose, which appears to have been at least a grain, is, we consider, large, taking into account the age of the children. Possibly the nurse used more than Holt knew, or perhaps the drug was impure. It is not surprising to hear that none of the children received notable benefit. Prior¹⁴ painted the pharynx and larynx with 10 per cent. solutions of cocaine, and also gave inhalations of 20 per cent. solutions. He obtained good results, but less so with the spray. Michael¹⁵ found it of some value. Schuch¹⁶ using 3 per cent. and 1 per cent. solutions, found it of doubtful value. Pott¹⁷ obtained excellent results from painting the pharynx with 5 per cent. solution. He has no fear of evil consequences even with infants six months old. W. L. Carr¹⁸ has frequently swabbed the throat with 4 per cent. solutions, and never totally failed to obtain benefit. He has never seen a case of poisoning. It will be noticed that all these observers use the drug purely as a local application. In this way it is apt to give rise to dryness of the throat, and is not nearly so likely, according to our view, to be of service as if given internally, for the too irritable centres are to be attacked rather than the small area of peripheral endings which one can hope to affect locally. Even on the theory of local action the method of swabbing, and still more so of spraying, the throat leaves comparatively untouched the nerve endings in the stomach, and vomiting is certainly one of the most troublesome symptoms of the disease. It is noticeable that more satisfactory results have been obtained by swabbing than spraying, as we should expect, for more of the drug is swallowed in the former method. Our practice is to give doses of hydrochlorate of cocaine in water based on the standard of a one-grain dose for an adult, three or four times a day by the mouth. We determined to try cocaine in whooping-cough on account of the following facts. Death in cocaine poisoning results from respiratory failure; Stockman,¹⁹ in his extensive investigation on the action of the coca alkaloids, says: "It is difficult to analyse the action of cocaine on the mammalia owing to the early occurrence of death from paralysis of the respiratory centre." H. M. Biggs²⁰ draws attention to the same fact in frogs and recommends the drug as indicated both in tetanus and strychnine poisoning. Many other observers might be cited in support of this paralysing effect. The question arises, What part is affected? We are inclined to think that the drug either paralyses the vagal centre or else excites some part antagonistic to it. Many of the effects of cocaine may be explained on the assumption that it acts on the sympathetic system, particularly the vaso-constrictor nerves; thus it dilates the pupils, causes peripheral vaso-constriction, and acceleration of the heart. In many respects we know that the sympathetic and vagus are antagonistic nerves, at any rate as far as the heart and intestines are concerned. In support of the sedative action of the drug, at least on a part of the respiratory centre, may be urged the good results which Mosler²¹ obtained from subcutaneous injections in cases of asthma. Many observers say cocaine increases the respiration; this we are not sure of; still, it is quite reconcilable with what has gone before, for possibly with a less excitable centre the respirations become more rapid and less deep. It is known that emotion, which one may conceive excites both the respiratory and cardiac centres, causes the respirations to be fewer and the heart's beats more frequent. Laborde²² found on injection of the hydrochlorate into the veins of rabbits that insensibility of the mucous membranes of the pharynx, larynx, and tongue appears. Most observers are agreed that it lessens the secretions, and its efficacy in vomiting is well known. Finally, it is remarkable that in some respects cocaine resembles atropine in its action, and belladonna is the drug which at the present time is perhaps most in favour for treating whooping-cough. Lauder Brunton,²³ speaking of cocaine, says: "The quickness of the pulse appears to be due to paralysis of the vagus, and the action of cocaine on both pulse and blood pressure is very like that of atropine." Unfortunately from the conditions

under which the observations were made it is impossible to present our results in a tabular form. When the children recovered the mothers frequently ceased to attend, though in as many cases as possible they were induced to continue for from six weeks to two months after the symptoms of whooping-cough had disappeared, so we are enabled to state that the improvement was permanent and not merely a temporary lull in the course of the disease. As whooping-cough is not admissible into the wards of the Hospital for Sick Children, Great Ormond-street—at which the cases were seen—a considerable number of cases were those of severe disease, with attendant broncho-pneumonia. The total number treated was 323, and as all first came under observation during the most unfavourable months of the year—namely, the late autumn and early winter of 1894—one would expect the course of the disease to be as long and unfavourable in these cases as it ever is; however, only two cases died, both under six months; one from broncho-pneumonia, and the other, in which cocaine was only tried as a last resource when other remedies had failed, from persistent vomiting, and the drug was only given for about two days before the fatal termination, which could in no way be attributed to its use. We may here mention that we have never seen any marked evil effects follow the use of cocaine; the only symptom which could in any way be construed as unfavourable was in some cases slight relaxation of the bowels, and this, we consider, rather beneficial on account of the constipation so often found in whooping-cough. The average duration of the disease under cocaine treatment is about three weeks; in slight cases it may be a fortnight or less—indeed, it seems as if pertussis may be made to abort in many of the slightest cases if the patient is seen and treated early. Of course, severe and more obstinate cases do occur where the disease is somewhat more protracted, but if these numbers are compared with the usual course it will be seen that the drug has a very marked effect in lessening the duration, which is generally stated at from six weeks to two or three months. The child, as a rule, when taking cocaine, soon begins to show great improvement in its general condition; the sickness, when present, stops, the anorexia disappears, the cough becomes less frequent, the sleep at night improves, and restlessness vanishes, but the whooping, while diminished, may persist for a fortnight, when it usually stops, never to reappear. The mothers, on coming a week after the commencement of the treatment, very often say: "The child is much better; it still whoops sometimes, but I do not mind that, for it is less frequent, and otherwise its health is much improved; the vomiting has stopped and appetite is good." Naturally, one does not expect that cocaine will cure broncho-pneumonia when that has developed, but even in these cases of complicated whooping-cough it seems to be of benefit, and children under its action do better than without. We now give notes of a few of our cases; these have not been specially selected, and give a very accurate representation of the whole number.

CASE 1.—A girl aged six years attended at the Hospital for Sick Children, Great Ormond-street, on Oct. 19th suffering from cough, which was worse at night, accompanied by either vomiting or expectoration, and when severe followed by whoop. The physical signs exhibited a few moist râles in the chest. The temperature was normal. There were loss of appetite and constipation. The patient was ordered cocaine hydrochlorate, a third of a grain three times a day. On Oct. 26th her mother described her as "almost well." The cocaine was increased to half a grain three times a day. On Nov. 9th the pertussis was quite cured. She was then ordered cod-liver oil and Parrish's food.

CASE 2.—A boy aged three and a half years attended at the Hospital for Sick Children, Great Ormond-street, on Oct. 16th suffering from well-marked whooping-cough. He had been ill with a "cold" and now had a severe spasmodic cough accompanied by whoop and expectoration. There were moderate constipation and anorexia. The temperature was normal. Cocaine hydrochlorate, one-fifth of a grain three times a day, was ordered. On Oct. 23rd the mother described the child as "much better." The cocaine was increased to one-quarter of a grain. On Nov. 2nd the cough was quite cured and the vomiting had ceased. Cod-liver oil and Parrish's food were prescribed, which the child continued to take for about a month, and he was then discharged.

CASE 3.—A boy aged five and a half years, brother of the preceding patient, attended on Oct. 23rd suffering from

whooping-cough. The symptoms were well marked. There were cough, whoop, expectoration, vomiting, and constipation. The temperature was normal. The eyelids were puffy, with suffused conjunctivæ. One-third of a grain of cocaine hydrochlorate was ordered three times a day. On Nov. 2nd the patient had improved in all respects. On Nov. 10th the cough was quite gone and there was no vomiting. The patient was then given cod-liver oil and Parrish's food. He was kept under observation for a month and then discharged.

CASE 4.—A girl aged three years attended on Nov. 5th suffering from whooping-cough, which had also attacked several other members of the family. The symptoms were severe spasmodic cough accompanied by whoop and always terminated by the expectoration of thick ropy mucus; he occasionally also vomited. There was constipation, the face was puffy, and the eyes were injected. One-fifth of a grain of cocaine hydrochlorate was ordered three times a day. After this the child improved so much that, contrary to instructions, the mother did not attend for a fortnight. On Nov. 19th the patient was greatly improved. The cough was still severe, but the vomiting had quite ceased. The dose of cocaine was increased to a quarter of a grain. On Nov. 29th the cough was much less, but the child was not yet quite well. On Dec. 3rd the cough was quite cured. She was given cod-liver oil and Parrish's food for six weeks and then discharged.

CASE 5.—A boy aged two years and seven months attended on Oct. 15th suffering from severe rickets complicated by pertussis. The child looked ill. There were some general bronchitis and severe night cough accompanied by whooping and vomiting. He was ordered a purge and one-sixth of a grain of cocaine hydrochlorate three times a day. On Oct. 22nd he was better, but the cough was still severe, and the medicine was repeated. On Oct. 31st the patient was still improving, but was not well, whoops still continuing. The cocaine and purge were repeated. On Nov. 9th he was much better and coughed very little. The medicine was repeated, and cod-liver oil, one drachm three times a day, was ordered. On Nov. 16th the cough was quite cured. He was given cod-liver oil and Parrish's food for a month, and then discharged.

CASE 6.—A male infant aged eight months was brought to hospital on Oct. 9th suffering from the effects of injudicious feeding and rickets, for which he was suitably treated. On Oct. 13th he was very ill and was heard to definitely whoop. There was general bronchitis and some broncho-pneumonic patches. The temperature was 101.6° F. There were vomiting and restlessness. The patient was given a purge, a cotton-wool jacket, creosote as a dry inhalation, and one-sixteenth of a grain of cocaine hydrochlorate three times a day. On Oct. 15th he was much better. The temperature was 99.4°; the cough was still severe, but the vomiting had ceased and the severer lung symptoms had abated. He was given a purge and the medicine was repeated. On Oct. 18th he was seen again, and improvement was continued. The temperature was 99.2°. He still coughed, but the child's general condition was vastly improved since the 13th. The dose of cocaine was increased to one-twelfth of a grain. On Oct. 25th the temperature was 99.2°. There was still some general bronchitis, with bronchophony over the right base. There was no vomiting, but occasional whooping. The cough was worse at night and of the pertussis type. General improvement was great, and the dose of cocaine was increased to one-tenth of a grain thrice daily. The purge was repeated. On Nov. 2nd the temperature was still 99.4°. The patient coughed much less, but occasionally whooped. The medicine was repeated, and one drachm of cod-liver oil was given twice daily. On Nov. 9th the temperature was normal, the cough had quite disappeared, and the child was perfectly well. Cod-liver oil and Parrish's chemical food were given for one month, after which the patient was lost sight of.

CASE 7.—A boy aged five years, brother of the preceding patient, attended on Oct. 15th suffering from pertussis. The case was a straightforward one, not complicated, like the preceding, by broncho-pneumonia. The temperature was normal. There were some fulness about the palpebral region and suffused conjunctivæ; spasmodic cough, worse at night; choking, terminating by expectoration; and frequent vomiting almost immediately after meals. There was no definite whoop. The patient suffered from anorexia and constipation. He was given a purge and a quarter of a grain of cocaine hydrochlorate three times a day. On Oct. 25th the mother described the child as "very much better." The vomiting had quite stopped, and the child coughed "scarcely at all." He had, however, definitely whooped after the last

visit. The cocaine was increased to one-third of a grain. On Nov. 2nd the child had quite recovered. He was given cod-liver oil and Parrish's chemical food for eleven weeks; he then ceased to attend.

CASE 8.—A boy aged two years and two months attended on Nov. 7th suffering from whooping-cough. The patient was a small, weakly looking child, somewhat rickety, with severe cough lasting several minutes. It was worse at night and produced vomiting. There were no definite lung symptoms beyond a few moist sounds. He was given one-sixth of a grain of cocaine hydrochlorate three times a day and dry inhalation of creosote. On Nov. 14th he was reported to be "much better"; the cough was much less frequent and less violent, and vomiting had ceased. He coughed and whooped occasionally. Cocaine was increased to one-fifth of a grain. On Nov. 21st there was continued improvement. On Nov. 28th he continued *in statu quo*. On Dec. 5th there had been a little more bronchitis since the last visit, but the whoop was practically absent. The medicine was repeated, and one drachm of cod-liver oil three times a day was ordered. On Dec. 12th the patient was better, and scarcely coughed at all. On Dec. 19th the cough was quite cured. Cod-liver oil and Parrish's food were given and continued for five weeks. The patient was then discharged. (The longer period of treatment necessary in this case was caused by a chill contracted either just before or after Nov. 23th; this complicated the results.)

CASE 9.—A girl aged four and a half years attended on Oct. 28th with symptoms of an ordinary cold. The temperature was 99.4° F. There were cough and slight watery condition of the eyes, but no rash; some moist sounds in the chest were present, but no consolidation. On this occasion it was not recognised as pertussis. The patient was given a purge, a cotton-wool jacket, and ipecacuanha mixture. On Oct. 30th she was no better, but there was no whoop or vomiting. The medicine was repeated. On Nov. 8th it was found that since the last visit the cough had changed in character and become spasmodic, being worse at night; on some occasions she had been heard to whoop. There was considerable expectoration. One quarter of a grain of cocaine hydrochlorate was given three times a day. On Nov. 23rd the child had improved so much on the cocaine that the mother, instead of attending in a week's time, allowed a fortnight to elapse, during which she continued the cocaine, and the cough was now quite cured. The patient was given cod liver oil and iron, and kept under observation for five weeks. She was then discharged.

CASE 10.—A girl aged three and a half years, sister of the preceding patient, attended on Nov. 23rd suffering from severe rickets, for which she was given cod-liver oil and Parrish's food. On Dec. 6th it was found that since the last visit the child had developed a cough, but there were no distinctive characters of pertussis. There were a few moist sounds in the chest. Ipecacuanha mixture was given. On Dec. 20th the temperature was 99.4° F. The cough was worse, accompanied by whoop and vomiting, and most severe at night. There was some general bronchitis. The patient got red in the face from the violence of the cough. One-fifth of a grain of cocaine hydrochlorate was given three times a day, also a purge and a dry inhalation of creosote. On Dec. 28th the cough was quite cured. She was given cod-liver oil and iron for a week, when the child was reported as "recovered."

CASE 11.—A boy aged five years attended on Oct. 16th suffering from severe symptoms of pertussis. The child looked ill. The temperature was 99.8° F. There was some general bronchitis, but no definite consolidation. The cough was severe and frequent, lasting several minutes, accompanied by whoop and terminated by expectoration or vomiting. Ingestion of food was always followed by vomiting. The patient suffered from constipation and had a furred tongue. The cough prevented the child getting any rest at night. He was given a purge, a cotton-wool jacket, and one-third of a grain of cocaine hydrochlorate three times a day. On Oct. 23rd he was reported to be "much better." There was no vomiting and the cough was less. The temperature was normal. On Nov. 2nd the temperature was 100.8° and the child looked very ill. There was general bronchitis, and broncho-pneumonia at the right base. The cough was very violent and was accompanied by epistaxis and hæmoptysis, with continual vomiting. The cocaine was increased to two-fifths of a grain; one drachm of cod-liver oil three times a day, and a dry inhalation of creosote were given, and the purge was repeated. On Nov. 13th he had much improved in general condition, though

the temperature was 99.2° and the cough severe. All the remedies were repeated and the cocaine increased to half a grain. On Nov. 20th the temperature was 100.6°. The cough continued, but the child was much better. On Nov. 27th the temperature was 99.2° and the cough much less. On Dec. 4th the temperature was 98.8° and the cough very slight and seldom. On Dec. 11th the patient still coughed occasionally, but otherwise was quite well. On Dec. 18th the cough was quite cured, and he took medicine and cod-liver oil for fourteen days and then ceased to attend. (It will be observed that this was a very severe case and complicated by broncho-pneumonia; hence the longer period of treatment necessary before recovery.)

CASE 12.—A boy aged three years attended on Sept. 24th suffering from follicular tonsillitis, which was suitably treated. On Oct. 3rd the throat was well, and tonics were ordered, which he took for a month. On Nov. 2nd the child began to exhibit symptoms of pertussis, severe "tearing" cough with occasional whoop, worse at night, and accompanied by expectoration, which on two occasions was blood-stained. He was ordered one-fifth of a grain of cocaine hydrochlorate three times a day. On Nov. 9th he was better, the cough was less, and the expectoration very slight. There was no vomiting, and the cocaine was increased to one-third of a grain. On Nov. 16th the patient was much better and coughed very seldom; he had decidedly put on flesh. The cocaine was increased to half a grain. On Nov. 23rd the cough was completely cured. The cocaine was stopped and the boy was given tonics. He was kept under observation for two months and then ceased to attend. (It will be observed that this case is one in which whooping-cough arose while the child was under observation for another affection.)

CASE 13.—A male infant aged three months was brought to hospital on Aug. 11th suffering from congenital syphilis and wasting, for which he was suitably treated and seen at intervals until Oct. 27th, when definite symptoms of pertussis declared themselves. There were cough and vomiting, and the patient again commenced to waste. There were some bronchitic sounds in the chest, and the mother said that the "cough nearly choked the child." One sixteenth of a grain of cocaine hydrochlorate was given three times a day. On Nov. 3rd the patient's condition had greatly improved. There were still coughs and whoops, but the sickness had ceased. The cocaine was increased to one-fourteenth of a grain. On Nov. 10th there was continued improvement; the cough was now only slight and occurred much less frequently. The cocaine was increased to one-twelfth of a grain. The improvement in the child's condition was so well maintained that the mother omitted to attend in a week's time, and the date of her next visit was Nov. 24th, when the cough was completely cured, so the child was ordered tonics, which he took for eight weeks and then ceased to attend. (This, like the preceding case, is one in which whooping arose during treatment for another affection.)

It will be observed that in most cases the children were kept under observation long after the symptoms had ceased. We hope these results may stimulate other observers to give cocaine a lengthened trial in similar cases, so that our conclusions may be either confirmed or refuted, and we feel we may say with Sir Thomas Browne: "This is the tenour of my belief, wherein, though there be many things singular and to the humour of my irregular self, yet if they square not with mature judgments I disclaim them, and do no further favour them than the learned and best judgments shall authorise them."

A HEAVY BRAIN.

By JAMES MIDDLEMASS, M.B., C.M. EDIN.,

SENIOR ASSISTANT PHYSICIAN, ROYAL ASYLUM, MORNINGSIDES.

It is now fairly well recognised that "superiority of size of brain cannot be regarded as a constant accompaniment of superiority of intellect."¹ Nevertheless, it is still a popular impression that there is a connexion of some sort between the size of the brain and the intellectual capacity of its possessor. The following case is of interest both on account of its being, so far as I can find, the heaviest recorded in Scotland, and because it may throw some light on the above question.

¹ Wagner: Vorstudien zu einer wissenschaftlichen Morphologie und Physiologie des menschlichen Gehirns als Seelenorgan.

The brain was that of a patient who was admitted to Morningside Asylum in 1852, at the age of thirty years. He was deaf and dumb and his vision was very deficient. He had for a number of years been able to do very little work except dig in the garden at times. He was very weak in mind, but he had been taught to speak a little on his fingers. This shows that his deafness was probably in existence very early in life. His disposition was variable, being at times very passionate, but on the whole he was easily managed. He was said to have suffered in infancy from hydrocephalus. Two years before his admission his mind, never very strong, began to lose much of its power and he became more imbecile. He at that time also suffered from chorea and had diplopia, but this gradually passed off. Just before his admission he became restless and inclined to wander about. He then had hallucinations of hearing and held conversations on his fingers with the voices he imagined he heard. He gradually developed delusions of persecution and became dangerous to those around him. Ultimately he escaped from home and created a disturbance in the street, which necessitated his removal to the police office, from which he was taken to the asylum. On his admission there was found to be no hereditary history of insanity, and his bodily health, except for the attacks of hydrocephalus in infancy and of chorea already mentioned, had been good. On account of his history and symptoms he was regarded as a case of idiocy due to hydrocephalus. During his residence of forty years in the asylum his history was comparatively uneventful. At first he had occasional attacks of excitement, but these ultimately ceased altogether. His vision, already impaired, became much worse, and after several years he became quite blind. He was, however, capable of speaking a little on his fingers, and was taught to assist in dressing and undressing other and helpless patients. Apart from this he did nothing, and his existence was almost purely negative. Indeed, during the last few years of his life it was purely so, as his mind seemed to be almost entirely gone. He died in June, 1892, at the age of seventy, from an attack of pneumonia.

Necropsy.—The following conditions were found. The head had a decidedly large appearance, and the circumference a little above the eyebrows was twenty-four inches. The shape was not that usually associated with chronic internal hydrocephalus, but was more rounded, with a high dome. The bones of the skull were considerably thickened, especially the inner table. The dura mater was slightly adherent all over the inner surface of the skull cap, and there was slight general thickness of its substance, with a distinct subdural membrane on the right side and rusty staining on both. The brain weighed immediately after removal 65 oz. This was at once recognised to be a very large weight and was carefully verified. The pia arachnoid was not milky, but presented a healthy appearance. There was no adhesion to the grey matter of the cortex. The convolutions appeared to be full and rounded, and there was no striking abnormality in the arrangement. The absence of atrophy is remarkable, considering the age at which the patient died—viz., seventy. The optic nerves and the auditory nerves had undergone degeneration and atrophy. When the brain was cut up there was no abnormality to be seen except a cystic condition of the choroid plexuses of the lateral ventricles and a slight dilatation of these chambers, which contained a little over 2 oz. of fluid. The pituitary and pineal bodies seemed to be normal. Sections were made from various regions of the cortex by Bivan Lewis's fresh method and were naturally examined with considerable interest. The following conditions were found in those taken from the anterior end of the left inferior frontal convolution, which may be regarded as typical of the others also. As regards the *grey matter*, the pia mater had a normal appearance, both as to thickness and the number of nuclei present in it. The outermost layer of the cortex showed a slight sclerotic change, there being a small amount of fibrillation, due to the processes of spider-cells. These were present in numbers somewhat more numerous than the normal and were faintly stained, and most of them had, in addition, distinct evidence of fatty change. They were apparently not in a very active condition and did not indicate any acute change. In the outer part of the fibrillar network there were a few colloid bodies. The nerve cells in all the layers showed decided pigmentary degeneration. Most of them were in the condition described by Bivan Lewis as characterising the second phase of the first stage of that cellular change. The cells were somewhat rounded in shape; the processes were still quite evident and took on the

stain well; the protoplasm was fairly uniform in appearance, but was beginning to retract; and the pigment was increased in amount and was more widely distributed over the cell than in the healthy condition. The neuroglia appeared to be normal. The protoplasm of the cells forming the walls of the arterioles and capillaries had apparently undergone a slight hyaline change, but there was little, if any, increase in the nuclei of the adventitial cells. There were small masses of pigment in the perivascular spaces of most of the arterioles. The number of cells in the grey matter did not appear to be increased, and the whole thickness of the cortex was not greater than is seen in the normal condition. In the *white matter* the chief morbid appearance and the one which immediately attracted attention was the presence of a number of delicate spider-cells all through its substance, but they were especially numerous in the parts near the cortex. They were faintly stained, though they could be made out with little difficulty and were quite distinctly morbid elements, being more numerous, better stained, and larger in size than the few which can be seen in the healthy state. As in the outer layer of the cortex, however, they did not indicate an acute process of any kind, and their function, whatever it may be, was apparently in a state of more or less quiescence. The vessel walls showed a hyaline appearance similar to that already described as existing in those of the grey matter, and in addition there was some nuclear proliferation in the adventitial sheath. The nuclei of the neuroglia were somewhat increased in number. The axis cylinders of the nerve fibres did not stain well and there appeared to be a slight increase in the size of their medullary sheath. They also appeared to be separated more widely than normal by the neuroglia substance. The structure of this material was not brought out by the method of staining, but it seemed that the separation of the nerve fibres was due to an increase of some sort in this portion of the white matter. This was also borne out by the appearance of the sections under the low power, as the white matter had then a more diffusely dark appearance than the normal, owing to the new material taking on the dye fairly strongly. In sections from other regions of the brain the changes above described were also present, with slight individual differences in the appearance of the cortex, but the white matter was everywhere the same.

Remarks.—The interest of this case is due in the first place to the fact that the brain weighed so much above the average, and that this occurred in a person who, to all outward appearance, might as well have had no brain at all, at least so far as its higher functions were concerned. It is, therefore, all the more necessary to endeavour to find some explanation of this apparent contradiction to a widespread general opinion. This seems to be found in the changes which were discovered to be present on the examination of sections. As stated above, the grey matter was to all intents and purposes normal to a person of the same age, so that the explanation must be found in the changes which the white matter presented. The exact nature of these changes is still uncertain, but a comparison with a case of so-called hypertrophy of the brain, which I lately examined and hope soon to put on record, seems to indicate that this case was also one of that disease. It is of course unusual for a patient affected with it to survive, but so little that is definite is known about its pathology and clinical symptoms that too much stress should not be laid on this fact. Any other explanation is at present impossible, and, though diagnosis by exclusion is often fatal to accuracy, I think there are also positive grounds for the opinion. Another point of interest in the case is the examination into the question as to whether atrophy of a sensory nerve is followed by recognised changes in the nerve cells of the cortex which are known to subserve the same sensory function. In this case, as already stated, both optic and auditory nerves were atrophied, and before death the patient had been blind and deaf for many years; yet a careful examination of sections from the regions generally recognised to be associated with sight and hearing—viz., the angular gyrus and first temporo-sphenoidal—did not reveal any material difference from those taken from other regions. This is quite on a par with my experience in three cases where a limb had been removed by amputation, and in which no characteristic changes were present in the corresponding motor cortex. This is somewhat different from what is known to follow section of a peripheral nerve, and is a proof (were any further needed) that the intercentral connexions between different parts of the nervous system are much more complex and numerous than

those between the periphery and the cord, or *vice versa*. A reference to previous recorded cases of heavy brain reveals the interesting fact that the heaviest of all was found in an imbecile, while several others of extraordinary weight, including the subject of this paper, have been those of inmates of asylums. Unfortunately in most cases no record of microscopic examination is given, so that it is impossible to say whether the weight was due to such an abnormal condition as has been described or not. That some morbid change would have been found if looked for may, I think, be safely asserted, and the necessity for such an examination in subsequent cases is all the more demonstrated.

Literature of the subject.—There is a reference in Hack Tuke's Dictionary of Psychological Medicine, article "Brain, Anatomy of," to a case recorded by Dr. Levinge. The brain weighed 1998 grammes (70.5 oz.) and belonged to an imbecile, an inmate of Hants County Asylum. The following may also be consulted:—Bergmann: "Einige Bemerkungen über das Gewicht des Gehirns" (*Allgemeine Zeitschrift für Psychiatrie*, 1852, vol. ix, p. 361); Boyd: *Philosophical Transactions*, 1861, cli., p. 241; *Brit. Med. Jour.*, vol. ii., 1876, p. 425; Sir J. Crichton-Browne: *Brain*, vols. i. and ii., 1879; Clapham: *West Riding Asylum Reports*, vols. iii. and iv.; Hills: *Proceedings of the Connecticut Medical Society*, 1878 p. 161; Lawson: *THE LANCET*, vol. ii., 1875, p. 306 (weight of brain of senile dement, 64 oz.); Marshall: *Journal of Anatomy and Physiology*, July, 1892; Morris: *Brit. Med. Jour.*, vol. ii., 1872, p. 464 (weight of brain, 67 oz.); Obersteiner: *Centralblatt für Nervenheilkunde*, 1890, p. 193; and Wilson: *Edinburgh Medical Journal*, January, 1891, p. 650 (weight of brain, 64 oz.).

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

RAILWAY OR TRAIN SICKNESS.

By J. A. SHAW-MACKENZIE, M.B. LOND., M.R.C.S. ENG.

INQUIRY elicits the fact that there are many who suffer from railway sickness. I am not aware that direct attention has been given to this special cause of *migrain*; I am satisfied, however, that the inconvenience is real and that there are many who are more or less knocked up by a long journey, and in whom a railway journey of two hours produces as much dread and misery as a sea passage. I venture to draw attention to the value of sulphonal in these cases, and to suggest its further and more extended trial in both railway and sea journeys. In children train sickness is common, while in adults railway *migrain* varies from undue fatigue and inability to sleep the same night to intense headache, sickness, and prostration coming on after some two hours in the train. The dose of sulphonal would vary, of course, according to the severity of the symptoms and the length of the journey. In my own case I find that ten to fifteen grains are sufficient for the day journey to Edinburgh, while twenty to thirty grains in divided doses are necessary for the night and day journey to the North of Scotland. The following cases are further illustrative. 1. A married woman who generally suffers from headache, nausea, and sleeplessness after a long journey took on starting fifteen grains of the drug. She travelled from London to Newcastle-on-Tyne on a day journey without headache and sickness, while refreshing sleep followed at night. 2. Another married woman who journeyed from Paris to Pau, on taking ten grains, felt well and fresh, while her governess and little boy, who are usually sick, travelled better and were not sick on taking ten and five grains respectively. She thinks a second dose might have been taken by them with advantage. 3. A single woman who journeyed from London to Cannes, after taking fifteen grains, did not feel the journey more than in going from London to York, though usually knocked up. I might say I have tried antipyrin, phenacetin, the bromides, and chloral, but have not experienced the same benefit as with sulphonal. An aperient dose the day before travelling is, I think, advantageous, while facing the engine or lying down is helpful. As to the value of sulphonal in sea-sickness

I can only produce three cases in its favour. Many patients who suffer from railway sickness do not suffer from sea-sickness, or only slightly. 1. A married woman travelling from London to Guernsey, who was usually sea-sick, after taking ten grains had a good journey and was not sick. 2. A single woman travelling from London to Flushing, who was always sea-sick in the calmest weather, after taking fifteen grains slept well and was not sick, arriving fresh. 3. A married woman travelling from London to Dublin, who had always been sick and dreaded the journey, after taking ten grains slept well, was not sick, and arrived altogether fresh and well.

FOREIGN BODY IN THE FOREARM FOR SEVEN YEARS.

By W. OWEN EVANS, L.R.C.S., L.R.C.P., L.M. EDIN.,
L.F.P.S. GLASG.

THE curious case about to be recorded came under my notice recently; it is that of a man who came to me complaining of most severe pain in his forearm. On examination I found the anterior aspect of the forearm to be very much swollen, livid, and indurated over a great area, at the centre of which was a small pin-head-sized opening, about four inches from the bend of the elbow. Before I proceeded further with the case I may say that this man met with a somewhat trivial accident some seven years ago, which resulted from a fall in trying to escape from a shot which was about to be fired down a coal-mine. The result of the accident was that the man had a small wound on the posterior aspect of his forearm, which bled profusely at the time. He immediately proceeded to the colliery surgeon, who dressed the wound, which healed in the course of a few days. After that the man returned to his work; but in about two years he complained of pain at the seat of the old injury, and, becoming unable to work, he again visited the surgeon, who painted the painful spot with various lotions and liniments, but without success. The patient, however, managed to go to work off and on until last September, when he was forced to give up owing to the most excruciating pain, sleeplessness, and anxiety. Up to two months ago he consulted various medical men, who advised rest and poulticing, but without success, and he came to my surgery as a last resource. As he said then, he at first avoided coming to me, being under the odd impression that I was a butcher and that I would remove his whole arm. At last he plucked up sufficient courage to come, with the result that I immediately probed the pin-head-sized opening to the depth of three inches and there detected a foreign body. Needless to say, I had to coax for a long time before I could get consent to make an incision. After great deliberation he gave in, and the result was that I began work and extracted with a slight twist of my dressing forceps an irregular piece of rock, which had become rooted in the depths of the forearm, weighing eleven and a half grains, half an inch long, and three-eighths of an inch broad in its widest dimensions. I dressed the wound with antiseptic dressings for five weeks, when it healed up well. The man has since resumed his duties with no ill effects except that he has had very slightly a peculiar tingling sensation in his little finger and half the next finger, the area which is controlled by the ulnar nerve. I attribute the tingling sensation to a slight twig of that nerve becoming attached to a little puckering at the corner of the wound.

Buckley, near Chester.

TEREBENE CONTRA-INDICATED IN GOUTY KIDNEY.

By CHARLES W. CHAPMAN, M.D. DUB.,
PHYSICIAN TO THE HOSPITAL FOR DISEASES OF THE HEART,
80, SOHO-SQUARE.

TEREBENE is so useful a remedy in some forms of chronic bronchitis that it is important to note any condition in which the exhibition of the drug may be harmful to organs which it is undesirable to stimulate. A man aged fifty-eight years, who had been subject to gout for many years and to bronchitis for the last eight winters, cough and wheezing being nearly always present, sought advice owing to the cooling in his chest disturbing his rest at night while

visit to the seaside. As the symptoms showed no signs of abating medical treatment was suspended, and the patient was directed to take simply ten to fifteen drops of terebene on going to bed and to repeat the dose at intervals if required. On his returning to town I was again consulted. I examined the urine and found it to be of the same low specific gravity I had noticed for a long time—1004; but in addition there was a distinct cloud of albumen. Thinking that the terebene might be responsible for the albuminuria I directed that the use of the drug should be discontinued for three days, and that some urine should be sent to me after that interval. This, on its arrival, was found to be absolutely free from albumen, and subsequent examinations have given the like negative result.

MIDDLESEX HOSPITAL.

A CASE OF CONGENITAL DILATATION OF BOTH URETERS; RIGHT URETEROTOMY AND LEFT NEPHROTOMY IN A NEW-BORN CHILD; REMARKS.

(Under the care of Mr. H. MORRIS.)

CONGENITAL hydronephrosis (usually affecting both sides) is sometimes found in the stillborn, or the subjects of it may live for several years; it is, however, a very fatal disease, and few patients survive their birth for many weeks. The fact of the existence of the condition proves that the secretion of urine goes on to a very considerable extent during the latter half of intra-uterine gestation, and that when any obstacle to the outflow of urine exists the same pernicious effects of distension of the bladder, ureters, and kidneys occur before birth as are commonly known to arise from urethral stricture, calculus, and other causes of obstruction after birth. The opportunity of attempting to prolong life in this condition has not often presented itself or been taken advantage of when it has done so, therefore the description of this case is of more than usual interest and importance. The following account is from the notes of Mr. E. Griffin, the dresser, who devoted much time and care to the case.

A male infant aged twenty-two hours was admitted to the Middlesex Hospital on Nov. 30th, 1893. The child was born at 6 P.M. on Nov. 29th and was brought to the hospital at 4 P.M. on Nov. 30th by an attendant, who stated that though the infant had passed a small quantity of faeces there had been no urine discharged, or, if any, only a drop or two. The midwife and mother had directed the child to be brought to the hospital, thinking he was suffering from "water on the stomach." Mr. Morris was asked to see him by Mr. B. H. Lee, the resident obstetric assistant at the time. The boy was small for a full-time child; he was well formed about the face and head, except that the right ear was somewhat misshapen; the legs and arms were very small, and the feet, like those of most new-born children, in a position of equino-varus. The abdomen was very greatly and irregularly distended, the distension being most marked in each anterior lumbar region and extending downwards towards the symphysis pubis. The lateral enlargements gave the impression of their being irregular oval cysts. They were dull on percussion, were greatly distended, and became tense when the infant cried. The remains of the umbilical cord were dried, and separation by ulceration was commencing. Extending downwards from the umbilicus in the middle line towards the symphysis pubis there was felt to be a hard cylindrical swelling connected with the abdominal parietes. The penis was enlarged, elongated, bent and twisted upon itself, and of a size more in accordance with that of a boy aged ten or more. On passing a finger into the anus the gut was found to be patent as far as could be reached, and on withdrawal some meconium stained the finger tip. A catheter slipped readily into the bladder, but the end could not be freely moved within it, and only a drop or two of blood-stained watery fluid escaped. The catheter

was kept in, anaesthesia was then induced, and an incision made above the umbilicus in the median line, large enough to admit the index-finger. The intestines were not distended; an enlarged urachus was felt as a resisting tubular swelling; and the two large lateral swellings appeared to lie behind the peritoneum. On compressing the abdomen about an ounce of quite clear fluid was discharged through the catheter, but the stream ceased in spite of abdominal compression, which made no appreciable effect on the distension. The laparotomy wound was then closed, and an incision made in each loin, a large urine cyst containing clear fluid evacuated on each side, and the cut edges of the cysts were stitched to the margin of the skin. After this the abdominal distension quite disappeared. Iodoform was sprinkled over the wounds and the infant wrapped up in cotton-wool. Next day he weighed 7½ lb. (with about ½ lb. of wool). The urine drawn off from the cysts was clear, pale, of sp. gr. 1004, faintly acid, and contained a trace of albumen, with phosphates, chlorides, and sulphates. The urea was 0.24 per cent. There was a free discharge of urine from the loin wounds, and on Dec. 3rd the child twice passed urine per vias naturales. The discharge from the loin was slightly bile-stained, and the infant's skin was jaundiced. The bowels acted. On the 6th he weighed 8 lb., with less wool than before. The jaundice had disappeared. The patient had been fed on cow's milk (one part) and water (two parts), with a little sugar of milk added. He was now given donkey's milk (a pint daily). On the 7th he passed urine per penem and a great deal through both loins. On the 13th, as the infant was not thriving, the food was changed. On the 14th his net weight was barely 5 lb. On the 17th some urine was passed at the umbilicus, through the urachus (the dried umbilical cord had separated on the 15th). On the 20th some pus welled up from the umbilical opening, and a slight amount also came from the penis; a probe was passed down the urachus for a distance of three inches into the bladder. On the 27th two distinct swellings were noticed in the abdomen, on pressing which much pus and urine came through the umbilicus and also through the loin wounds. On Jan. 1st, 1894, the infant weighed barely 4½ lb. On the 7th it was noted that the infant was slowly wasting, although a variety of diets had been tried, including cow's milk and water, ass's milk, humanised milk, &c. The last addition to the diet was six drachms of port wine daily. The infant, however, showed signs of intoxication with this quantity, and it was accordingly reduced to ten minims every four hours. On the 12th an ounce of cod-liver oil was rubbed in daily, and on the 17th the net weight was 4½ lb. On the 28th a slight discharge of pus from the umbilicus was noted. The infant weighed 5 lb. The urachus was smaller than on admission. On Feb. 8th no urine had passed for a fortnight from the umbilicus. Another kind of food was ordered. On the 23rd the child weighed only 4½ lb. On March 1st he was attacked with severe diarrhoea, and he died on the next day—the ninety-fourth day after the operation.

Neuroscopy by Dr. VOELCKER.—The following conditions were found. The body was very emaciated; there was a wound in each loin 1 cm. in length, and 2 below the last rib. There was a linear median scar above the umbilicus. The penis was long, 4.5 cm. in length, and bent and twisted upon itself, bowed with the convexity to the right, the urethral orifice appearing as a horizontal slit. The glans penis appeared on manipulation to be natural. On opening the abdomen both the testes were found to be lying high up in the inguinal canal. The allantois was patent and dilated, 1 cm. in diameter and filled with thick creamy fluid. No communication could be made out between it and the bladder, from which it was closed abruptly. The intestines were natural; there was a small Meckel's diverticulum 46 cm. from the ileo-caecal valve. The liver, spleen, and pancreas appeared to be normal. On raising the peritoneum the perirenal tissue was found to be condensed and the kidneys somewhat firmly bound down. The ureters were enormously dilated and ran a tortuous course. On the right side the ureterotomy wound was found to lead directly into the first convolution of the ureter and on the left side the nephrotomy wound had opened into the pelvis. The right kidney appeared to be somewhat cuboidal in shape and to be rotated round a vertical axis, so that its posterior surface looked inwards and somewhat forwards. The suprarenal capsule appeared to be normal and lay at a considerably higher level than that of the left. The right ureter at first ran behind the lower border of the kidney and was 1.2 cm. in diameter; in this

position it was firmly bound down to the abdominal wall and marked the position of the ureterotomy; it then took a convoluted course downwards to the right iliac fossa, gradually increasing in calibre, being at its widest part 2.5 cm. in diameter opposite the iliac crest. It then turned sharply on itself upwards, getting narrow, and finally bent down again, abutting against the rectum, and opened into the bladder at the usual situation. The *left kidney* had the usual reniform shape, but the pelvis of the kidney had been pulled backwards by the nephrotomy and formed an acute angle with the ureter. The left ureter coursed at first behind the lower half of the kidney, being in this situation of the same diameter as that on the opposite side. It took a somewhat straighter course downwards into the left iliac fossa; it then was bent

A, Convoluted ureter. B, Testicle. C, Bladder opened on its posterior wall. D, Convoluted ureter. E, Testicle. F, Remains of urachus turned down with the abdominal wall.

upwards on itself, forming an extremely acute angle, turned over the left hypogastric artery, and ran downwards again, coming into contact on this side also with the rectum, and opened into the bladder normally. On this side likewise the widest part of the tube was opposite the highest point of the crista ili and measured 1.8 cm. The walls of the bladder were much hypertrophied, and its cavity was contracted.

Remarks by Mr. H. MORRIS.—The points of pathological interest are (1) the distorted, enlarged penis; (2) the hypertrophied bladder; (3) the enormously and irregularly distended, and convoluted ureters, with well-formed kidneys; and (4) the enlarged and patent urachus. It would seem that the latter three conditions were caused by the first mentioned. It should be stated that on first attempting to pass the catheter it met with a ledge-like obstruction about two inches from the meatus, but this was readily overcome by untwisting and straightening out the penis. As a secondary effect of the distension of the ureters, the kinking of these tubes further increased the obstruction in them. The points of clinical interest are (1) the peculiar shape of the abdomen; (2) the large-sized urachus at birth; (3) the subsequent partial closure and suppurative of the urachus; and (4) the early age at which these triple operations were borne and the length of life—ninety-four days—of the child with these defects.

ANCOATS HOSPITAL, MANCHESTER.

CASE OF NEPHRECTOMY FOR CYSTIC KIDNEY; RECOVERY;
REMARKS.

(Under the care of Mr. E. STANMORE BISHOP.)

THIS case is one of hydronephrosis probably due to a kink in the ureter. The changes induced in the renal tissue made it necessary that the cyst should be excised and not simply incised and drained. Such a procedure, although still recommended in similar cases by some of our text-books, would have been quite useless where the disease was so advanced as in this instance. There is little doubt that the diminished mortality after nephrectomy, especially nephrectomy as performed through a lumbar incision, has much to do with the greater boldness now displayed in attacking such a diseased organ. This disease of the kidney is one in which the lumbar operation is especially indicated, and the mortality should not much exceed that which follows ovariectomy at the present day, as compared with that given by Newman (30.5 per cent.) and that by Gross (36.93 per cent.) for all cases of nephrectomy by this route.

The patient, a single woman aged twenty-one years, was sent to Ancoats Hospital by Dr. Wm. Armstrong of Buxton on Feb. 12th, 1895, complaining of a tumour in the right side of the abdomen. Her family history was good. There was no history of carcinoma or tubercle. Her catamenia had always been regular, very little being lost. They commenced when she was eighteen years old. There was some little premenstrual pain. Two years ago she first noticed some swelling, mainly after taking food. There was also aching pain in the anterior axillary line, midway between the ribs and ilium. The swelling diminished a good deal from time to time, but never entirely disappeared. When the aching pain came on—about once in three months—she had to go to bed and be poulticed, which relieved her. These attacks were becoming more frequent. She had had three bilious attacks, vomiting bile, coincidently with the pain. There was never any oedema of the legs or jaundice. She had always passed urine freely and had noticed no deposit in it until very recently. She remembered no accident. Her work had always been light. The measurements were as follows: circumference at the level of the tip of the sternum, 29½ in.; the same at the umbilicus, 33 in.; the same midway between the above, 28½ in.; half circumference at the level of the umbilicus, left, 16 in.; right, 15½ in. The tumour, which was easily seen and felt, lay in the right lumbar region, extending as far forward as the umbilicus, with a clear percussive note between it and the liver dulness. Percussion was dull over it. Its longest diameter, which was transverse, was 9½ in.; its widest vertical diameter at its anterior edge was 5 in., diminishing gradually to 3 in. behind. The surfaces were smooth, elastic, and rounded. No notch was to be felt. There was no pain on palpation and no sensation of nausea. The tumour moved with respiration, and whilst immovable to any extent upwards or downwards by external pressure, had fair lateral movement. It could not, however, be displaced backwards into the renal region. The urine contained a small quantity of blood and pus, recognised by the microscope and the guaiacum test. Recto-abdominal examination showed that the tumour did not spring from any pelvic organ. The diagnosis appeared to lie between greatly enlarged gall-bladder and omental and renal tumours. On Feb. 22nd, Dr. Armstrong being present, an exploratory incision (Langenbuch's) was made over the tumour. It was found to be beneath the peritoneum, the ascending colon being pushed over to the left side, the omentum drawn up and the tumour, covered by peritoneum, presenting at the opening. The peritoneum was closed and the patient turned over on to the left side. A second diagonal incision six inches long was made at the junction of the upper and middle thirds of the loin. After the muscles had been divided the tumour, dark chocolate in colour and very tense, presented. It was separated all round by the finger and scissors, the perirenal fat being all absorbed. When free, and pushed outwards by the assistant's hand over the abdomen, a small opening was made and a straw-coloured fluid gushed out. About a third was lost, but thirty-six ounces were collected, being of sp. gr. 1.002. It was neutral and contained albumen and chlorides, with small amounts of blood and pus, but no crystals or epithelium. The tumour collapsed and was easily drawn out. The ureter appeared

to spring from the lower extremity of the tumour and in its then position lay partly curved over the lower third of the tumour. It was not dilated. It was separately tied with a silk ligature. Another ligature was placed around the vessels and the tumour cut away at a short distance. Several small vessels still bled in the walls, and were tied separately. A large drainage-tube was placed in the cavity beneath the diaphragm. The action of this muscle produced a great deal of pumping in and out of air, this being drawn into the loose folds of connective tissue and expelled with some force. A small opening into the peritoneum was closed by catgut. The exterior of the ascending colon could be seen. The muscular layers of both incisions, and especially the fascia, were united by buried silkworm gut sutures, and the skin by horse-hair. Both were dressed with iodoform gauze and covered by wood-wool, and a flannel bandage was tightly applied. The operation, which was done on a hot-water table, lasted one hour and a quarter. The patient bore it well, and left the table with a good, full pulse—viz., 108—respiration 32, and temperature 96° F. A nutrient enema with brandy was given directly after the operation, and repeated every six hours. A catheter passed four hours after the operation removed thirteen ounces of clear urine. Collapse came on about one hour after the operation, and lasted for about an hour. About eight hours after the operation she complained of great pain under the diaphragm on the right side, but was relieved by four minims of the hypodermic solution of morphia. There was some nausea during the night, but no vomiting. At 6 P.M. the temperature was 97°, the pulse 98, and the respiration 23. A catheter was passed every eight hours. At 1 A.M. on the 23rd three ounces of urine were withdrawn, at 9 A.M. six ounces, and at 5 P.M. six ounces, and so on. The urine became loaded with urates after the first evacuation. On the next day (the 23rd) a teaspoonful of hot water was given every hour from 10 A.M. At 1 30 P.M., there being no sickness, half an ounce of milk and soda water was given, and at 5.30 P.M. half an ounce of beef-tea. On the 24th an enema had a slight result. On the 25th a punctiform rash resembling measles showed itself on the chest and legs, but there were no coryza or bronchitic symptoms. The urine was slightly alkaline. On the 27th, although no discharge showed itself outside the dressing, there being a slight sour smell the dressings were changed, and the large tube was replaced by one of smaller calibre. There was some puriform discharge. The amount of urine on this day was 32 oz. and alkaline. On the 28th it was 25 oz., and on March 1st 59½ oz. The rash had gone. On the 2nd the patient passed urine naturally for the first time. On the 3rd the urine was clear and acid and of sp. gr. 1020. On the 5th the stitches were removed from the wounds. The anterior wound was perfectly healed. The drainage-tube in the posterior wound was pushed outside and was not replaced. From this time the patient's progress was uneventful.

Remarks by Mr. STANMORE BISHOP.—I am glad to see that it is becoming the fashion to mention the name of the nurse in conjunction with any case in which her skilful co-operation has been of conspicuous value, and I have much pleasure in expressing my sense of the importance of Nurse Ward's help in the treatment of this case. Her constant attention, and especially her care to assure the perfect asepticity of the case from first to last, deserves all praise, and it is greatly due to her that the patient is now in perfect condition. As is evident from the specimen, the kidney has been reduced to a mere sac represented by the tightly distended capsule. The secretory tissue is only shown by a congeries of vessels in the fundus of each lobular dilatation. No calculus or any new growth was discovered. There had been no history of the passage of a stone, and the normal calibre of the ureter, as far as it could be seen, appeared to disprove any idea of a calculus wedged below. Moreover, the absolute freedom from pain since the initial soreness had passed off tells against the presence of any such cause. What, then, had produced this cystic degeneration? I suggest that it was, in the first place, a wandering kidney, and at the same time one with an abnormally placed ureter; that when its superior extremity moved downwards and forwards the ureter was bent sharply upon itself, forming a valve-like closure at its very origin; and that as urine accumulated in its pelvis and the kidney began to enlarge this bend would become more and more watertight, whilst the secretory tissue would, of course, under the intra-renal pressure, become gradually

absorbed. Removal appeared to be the only reasonable treatment, and was the more justifiable since all secretion had evidently been for a long time performed entirely by the other kidney, and the prolonged period necessary for such complete absorption of the secretory tissue in the right kidney would have given the left ample time for compensatory hypertrophy.

LEEDS GENERAL INFIRMARY.

A CASE OF SYMPHYSIOTOMY; REMARKS.

(Under the care of Dr. BRAITHWAITE.)

THE operation of symphysiotomy appears to have been introduced by Sigault in 1768, and performed for the first time in 1777 by Sigault and Lerz, but did not obtain much support from the profession. Its revival under more favourable conditions of wound treatment by Professor Morisani of Naples in 1890 has caused a further trial to be made of its value in certain cases of deformed pelvis. We published in THE LANCET in 1893¹ a list of Professor Pinaud's cases, thirteen in number, all of which were successful, and have also given a case under the care of Dr. Lewers.² The most complete account of the operation of symphysiotomy which is now available for reference is probably contained in the paper by Mr. C. Hubert Roberts in the last volume of St. Bartholomew's Hospital Reports.³ He mentions some cases which are not yet published, and as a result of his consideration of the subject proposes the following as the necessary conditions: (1) the woman must be at full term; (2) she must be in labour and the cervix fully dilated; (3) it must not be a desperate case—previous exhaustion, obstructed labour, high temperature, and sepsis contraindicate it; (4) the child must be alive when the operation is commenced; (5) the pelvis must not have a conjugate vera below three inches; and (6) the separation must never exceed two inches. For the notes of this case we are indebted to Mr. F. Walker.

A woman aged twenty-eight years, primipara, was sent to the Leeds General Infirmary on the evening of Nov. 25th, 1894. She had then been in labour eleven hours, and it had been found impossible to deliver her by forceps, owing to contraction of the pelvis. The membranes had been ruptured some hours, and the fully dilated os had receded over the fetal head, which was resting on the brim, so as to be felt with difficulty. The pains had for some hours been strong, but on the patient's admission were feeble. Her condition, however, was fairly good. The pelvis was found to be contracted antero-posteriorly, the true conjugate diameter being three inches and three quarters. On her being put under chloroform the forceps were again tried, but without success, and symphysiotomy was then decided on. The incision made was only an inch and a half in length—central, of course—and its lower edge just touched the upper border of the pubic symphysis, behind which the finger was then passed, gently but freely separating the soft parts to the lowest border of the joint. An ordinary probe-pointed hernia knife was used to divide the cartilage, the trochanters being at the same time firmly held together lest the bones should spring apart too suddenly. It was found quite impossible to divide just the lower edge of the cartilage and fibrous tissue with the knife because its cutting edge could not be brought to bear upon it owing to the depth of the wound. Traction was then made upon the head by the forceps, which had been left *in situ*, when the remaining portion of the cartilage broke audibly, and the head was delivered without any difficulty. When the parts were stretched to their widest it was attempted to measure the amount of separation of the pubic bones, but the wound was so closed by the pressure upwards of the post-pubic fat that the finger could not be inserted, and it could only be estimated by pressure on the skin over the divided symphysis that the separation was about an inch and a half. The wound was closed by deep silkworm gut sutures. The child lived, and is, or was when the patient left the hospital, quite well. The mother rallied well, and the bones reunited, so that for a week before her discharge in the third week of January she was able to walk about the ward—of course, with care and slowly. The bones were kept together by a "working man's belt," the belt commonly worn by workmen

¹ THE LANCET, Feb. 18th, 1893.

² THE LANCET, Aug. 5th, 1893.

³ Vol. xxx., 1894.

to enable them to dispense with braces. It has three buckles and straps, and is about six inches wide. It can be bought at any clothier's shop for a shilling.

Remarks by Dr. BRAITHWAITE.—The points brought out or illustrated in the above case are the following: 1. That something stronger and more curved at the point is required than a delicate probe-pointed hernia knife. Morison's symphysiotomy knife is admirably suited for its purpose. 2. That by making the incision above the symphysis and leaving the skin intact over it external support and pressure are given to it, and at the same time sepsis from the subsequent lochial discharge is avoided. 3. That the way to avoid hemorrhage is to gently but freely separate the soft parts behind the symphysis before dividing it, by which plan the stretching of the soft part is lessened in amount and distributed over a larger area. It would also be a good plan to put a few turns of bandage round the hips—not tightly—so as to prevent the separation of the symphysis occurring too suddenly. The operation is extremely easy if there is a suitable knife, but on an emergency in a country practice a sharp penknife would do. It is well to keep close to the bone so as to avoid wounding the bladder.

Medical Societies.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Prognosis of Cerebral Hemorrhage.—*Symphysiotomy.*—*Antitoxin Treatment of Diphtheria.*—*Exhibition of Cases and Specimens.*

A MEETING of this society was held on May 3rd, Dr. WEST SYMES being in the chair.

A paper was read by Dr. BARRE on the Prognosis of Cerebral Hemorrhage.

Dr. BRAITHWAITE read an account of a successful case of Symphysiotomy.

Dr. MANTLE of Halifax read a paper on the Antitoxin Treatment of Diphtheria and related two successful cases treated by this method. Case 1, a child aged four years, was seen on Feb. 18th evidently suffering from a mild attack of diphtheria. Both tonsils were swollen and upon each was seen a small patch of membranous exudation. The temperature was only slightly elevated, the pulse quick, the submaxillary glands enlarged, but there was no albuminuria. A cultivation of the bacillus made at the British Institute of Preventive Medicine, to which institution a portion of the membrane was sent, proved the case to be one of true diphtheria. The throat condition remained much the same for six days, but the left nostril then showed signs of obstruction and there was a sanious discharge from it, proving the mucous membranes of the nose to be also affected. The child all this time showed but little constitutional disturbance, the temperature never being over 100° F.; and although a supply of antitoxin serum was obtained it was not used, the symptoms being considered comparatively mild, but the usual local germicidal remedies were adopted and perchloride of iron was given internally. On the eighth day a very marked change in the condition of the patient took place. The temperature suddenly rose to 103.4° and the pulse to 140, and the heart was much embarrassed, a systolic murmur being heard at the apex and base. The child was evidently in a grave condition, and the friends consented to the injection of antitoxin; 10 c.c. were injected into the buttock. In fifteen hours the nose was perfectly clear, and at the end of twenty-four hours the temperature had gradually fallen to 99°, and the right tonsil alone showed a little membrane, the left being clear. Although the membrane had quite disappeared and the temperature was 99° next day a second injection was urged, but the friends refused it. A rise in the temperature to 102° occurred the following day, and fresh membrane was seen on the right tonsil. A second injection of 5 c.c. was then allowed under chloroform, after which the throat cleared and the temperature became and continued subnormal. The murmurs were still heard, proving them to be of endocardial origin, but otherwise the child made an excellent recovery. Case 2, a boy aged nine years suffering from hip-joint disease, was one of several patients in the children's ward of the Halifax Infirmary who suffered from sore-throat produced, as in Case 1, by

frozen drainage. On both tonsils there was seen membrane which on examination showed the bacillus of diphtheria. The temperature was not more than 100° F., the glands under the jaw were enlarged, but there was no albuminuria. As in Case 1, local and constitutional treatment were used, but there was every evidence of the larynx becoming involved and 2 c.c. of Behring's antitoxin were injected, the house surgeon being instructed to perform tracheotomy if the symptoms became very urgent. Next morning the breathing was markedly better and the membrane on the throat very much less, but a second injection was given. The following day, the ward being closed, the child, whose breathing and throat were still better, was removed to the fever hospital, but the medical officer stated that no more membrane was seen, and the patient made a good recovery. Dr. Mantle, having discussed the lines of thought by which investigators have been led up to the discovery of the antagonistic nature of toxins and antitoxins, expressed strongly the opinion that inasmuch as it has been proved that the bacilli do not enter the tissues, but are found chiefly near the surface of the exuded lymph, local germicidal treatment, and preferably the application of bichloride of mercury to the fauces, was most important in order to destroy these bacteria. The injection of antitoxin merely neutralised the toxins produced by the bacilli after becoming absorbed by the blood and tissues, but was most powerful in its action.

Cases and pathological specimens were shown by Drs. Solly and Moullot, Drs. Hallier, Mantle, Barra, Griffith, Bronner, and Churton, and by Messrs. Robson, Littlewood, and Robinson.

Reviews and Notices of Books.

The Elements of Pathological Histology, with Special Reference to Practical Methods. By Dr. ANTON WEICHELBAUM, Professor of Pathological Anatomy and Director of the Institute of Pathological Anatomy in the University of Vienna. Translated by W. R. DAWSON, M.D. Dub., Demonstrator of Pathology in the Royal College of Surgeons, Ireland. London: Longmans, Green, and Co. 1895.

THIS work forms a welcome addition to the already extensive literature on pathological anatomy, and we may at once congratulate Dr. Dawson upon having introduced it to the English-reading community of laboratory workers; for it is essentially a laboratory manual, although arranged on a plan which will make it useful also as a text-book upon pathological histology. The descriptive text, abundantly illustrated by engravings and plates that lack nothing in point of delicacy and finish, covers the whole ground, a due proportion in the subjects being kept throughout. Of necessity a book primarily intended for practical instruction, there is not to be found in it such detailed description of morbid changes as we are accustomed to meet with in books of wider scope, yet we think that no one will study its chapters without gaining a very wide and accurate insight into the nature and results of pathological processes.

In reading such a book as this the mind involuntarily contrasts the teaching of morbid anatomy of to-day with that which prevailed more than a generation ago when Professor Weichselbaum's distinguished predecessor in the Vienna chair, Carl Rokitanaky, produced his famous treatise, a work now almost forgotten, and yet one which gave a great impetus to pathological study all the world over. Attention was at that time rivetted upon gross and obvious changes in tissues and organs, and terms that sound crude to us were employed to denote lesions of whose true nature nothing was really known. Theoretical and, as it seems to us now, fanciful speculations were invoked to explain the results that met the unaided eye. The microscope was not, it is true, disregarded, but its use was limited, and it served to carry knowledge but little farther than did observation without its assistance. Indeed, the growth of pathological inquiry has been one of gradual evolution, and thanks to the firm foundations which were

laid by the pioneers in this study from Morgagni to Rokitsansky there was ready to hand a firm basis for the upbuilding of the more delicate superstructure of histology which now claims so large a share of attention. The perfecting of histological methods and the far-reaching application of the microscope, which has unfolded to view the new and ever-growing domain of bacteriology, are surely among the most striking advances in science made in a half century notable for scientific progress. The insight which histology has given into normal and morbid changes extends beyond the anatomical, for in many directions it has led to a more correct appreciation of the vital processes that initiate structural phenomena. Nevertheless, marked as the advance has been, we do not agree with those who, in these latter days, seem to think that finality has been reached, and that nothing remains to be discovered in the field of morbid anatomy. On the contrary, we believe that we are still on the threshold of researches into the physiology and pathology of cell-life which will open up still wider vistas and solve many problems of vital importance to the true conception of health and disease. The classical work of Rokitsansky marked an epoch in pathological study; the manual before us marks the utmost limit to which the same study has reached at the present day. Perchance the Vienna Professor of fifty years hence will produce a work on the same subject which will contain a record of facts as strange to the pupil of Weichselbaum as the teaching of the latter would sound in the ears of the pupil of Rokitsansky.

We must turn from these not unnatural reflections, however, to the book the perusal of which gave rise to them. Its plan is methodical and systematic. The first part deals with Methods of Investigation—first, with that of Histology, and, secondly, with that of Bacteriology. The instruction is at once simple and practical, free from any redundancy, but strictly confined to the matter in hand. It is clearly the work of one thoroughly conversant with all the technique of modern microscopical work, and may be taken as a safe guide in its numerous details. The editor has added an useful note upon the "Gum-freezing" Method, to which no allusion was made by the author. The bulk of the work is occupied by the systematic description of subjects coming under the head of General Pathological Histology (which includes also a terse but sufficient account of Micro-organisms), and then follow chapters upon Special Pathological Histology. Appended to each section of descriptive matter are paragraphs in smaller type giving an account of the methods most appropriate to the examination of the lesions described. As an example of the style of the text we may quote a few passages descriptive of a disease associated with the name of the author, whose work in the study of its micro-organisms is so well known—we mean Pneumonia:—

"Lobar or croupous pneumonia, also known as true pneumonia, is in the great majority of cases caused by the diplococcus pneumoniae, and only in a few instances by the bacillus pneumoniae or streptococcus pyogenes, or by a combination of two of the bacteria named. Even the lobar pneumonia which occurs in the course of other diseases—notably those of infective origin—may be due to the diplococcus pneumoniae, or to such bacteria (streptococcus or staphylococcus pyogenes and perhaps also bacillus typhosus) as are already present in some other organ in the particular disease. The latter bacteria then exist in the pneumonic lung either alone or along with the diplococcus pneumoniae. The form of pneumonia caused by the sole action of the diplococcus pneumoniae has a tendency to spread rapidly over considerable sections of the lungs, but may sometimes also take a more local form when occurring in the course of other infective diseases. The latter mode of appearance is especially characteristic of pulmonary inflammations caused by the streptococcus or staphylococcus pyogenes. In all these pneumonias we find in the alveoli, alveolar passages, and bronchioles, an exudation of somewhat variable

composition. At the commencement it is merely serous—i.e., in sections of hardened preparations a finely granular mass is found, with which are mingled isolated leucocytes, as well as desquamated epithelial cells, either large and squamous or small, and not uncommonly containing fat-droplets. The capillaries in the walls of the alveoli are also turgid with blood at this stage. Later, not only do the leucocytes in the exudation increase in numbers, but besides red corpuscles there appear more or less abundant fibrin filaments, delicate and difficult to recognise, or thick and with sharp outlines; and this is especially the case in pulmonary inflammations due to the diplococcus pneumoniae, whereas in pneumonia excited by the streptococcus or staphylococcus pyogenes the exudation is much less rich in fibrin. The red corpuscles in the exudation and the hyperæmic condition of the capillaries give the inflamed pulmonary tissue its red colour, whilst the granular appearance of the cut surface of the lung is due to the richness of the exudation in fibrin (red or brown hepatization). An exudation similar to that in the alveoli is also found in the lymphatics of the lungs, and further, the fibrinous mass which forms in the bronchioles may sometimes advance into the nearest branches of the bronchi, though the latter are not usually completely blocked by the exudation. The still larger bronchial ramifications show as a rule the appearances of an acute catarrh."—P. 278.

The above gives a fair example of the limits within which the author confines his work. He writes with the single aim of describing histological changes only, and he does not enter into needless disquisitions. The teaching is therefore dogmatic, but so good teaching must needs be. The student has to be instructed upon definite facts, and it will be time enough to amplify and dissect them when he has grasped them fully. We can warmly commend this work, which we think will prove of great service both to teachers and pupils. It is clear, accurate, and concise, and, as it should be, is thoroughly practical. We may regret the use of such a barbarism as the term "vasculitis," but this is a venial and comparatively unimportant *lapsus* in a work singularly free from such solecisms. The translator has done his task admirably, whilst the manner in which the work has been produced is worthy of the publishing firm that has issued it.

Atti dell'XI Congresso Medico Internazionale. Roma, 29 Marzo—5 Aprile, 1894. (Proceedings of the Eleventh International Medical Congress; held at Rome, 1894.) Vols. II. and III. Roma: Tipografia della Camera dei Deputati. 1894.

IT was announced in THE LANCET of Jan. 5th, 1895, that the Proceedings of the Medical Congress at Rome would be ready in April, and the appearance of these portly volumes, of more than 600 pages each, is the fulfilment of the promise. A loose leaf inserted in Vol. II. states that the issue of the Transactions to those entitled to receive them commences "with the present volume." Italian is naturally the predominant language; very many papers, however, are in German and French, a few in English, and at least one is in Spanish. Vol. II. contains the headings Anatomy, Physiology, General Pathology, and Pathological Anatomy. The anatomical memoirs include articles on the Skull of the Horse, by Professor Staurenghi of Pavia; on the Segmentation of the Ovary of *Seps Chalcoides*, by Professor Todaro of Rome; on the Coexistence of Pigmy with the tall European Races during the Neolithic Period, by Professor Kollmann of Bâle; and on the Osteology of the Anthropoid Apes, by Professor Waldeyer of Berlin. Professor Jimenes of Madrid recommends for anatomical injections a solution of 5 parts creosylic acid in 500 parts of glycerine, to which 500 parts of alcohol are subsequently added. Under physiology Dr. Lo Monaco of Rome gives an account of Experiments on the Excretion of Nitrogen and Phosphoric Acid during Chronic Poisoning with Phosphorus; and, in conjunction with Dr. Dutto, contributes an article on Fasting Men, illustrated by tabulated observations recorded during two prolonged fasts undertaken by Succo.

Professor Stefani of Padua gives the results of Five Years' Experiments on the Physical and Physiological Alterations in the Capacity of the Bloodvessels. Mr. F. Macdonald of London has a short communication (in English) addressed mainly to veterinary surgeons, on Transplantation of the Recurrent Laryngeal Nerve. Professor Lambing of Lille states that the spectroscopic examination of blood gives discordant results, varying with the instruments employed. Dr. Corso of Florence has found that fish are practically unaffected by removal of the cerebellum. The bulky section of Pathology has many contributors. Professor Lambi of Warsaw describes the Effects of Rickets in the Vertebrae. Professor Arloing and Dr. Chantre of Lyons give the results of their investigations into the nature of Parulent Infection following Surgical Operations; they find that the active agent is a streptococcus akin to that of erysipelas and puerperal fever. Professor Sirena of Palermo gives some hundreds of measurements of the body of an Egyptian, 7 ft. 10 in. in height, who died of parenchymatous nephritis in his twentieth year. Dr. J. Hawtson describes (in English) the organisms observed in the blood of 531 patients suffering from malarial fever and treated in the Johns Hopkins Hospital, Baltimore. Professor H. Manley of New York writes (in English) on Traumatic Lesions of the Spine and Spinal Cord. He has seen nothing to support the view that a railroad injury of the spine possesses uniform characters peculiar to itself. Professors Ch. Bouchard and A. Charrin of Paris contrast the virulence of the bacillus pyocyanogenus with the comparative harmlessness of the *Osipora Guignardi*. Professor H. Roger of Paris describes the Lesions and Derangements of the Liver in certain diseases; he concludes that the liver by transforming bacterial toxins acts as a protection against the morbid influence of bacteria. In the section on Diseases of Children, with which Vol. III. opens, there are contributions on the Pathology of Diphtheria, by Professor T. Escherich of Graz and Professor A. Baginsky of Berlin, and on the Serum Treatment of the same disease by Professor O. Heubner of Leipzig. Professor G. Mya of Florence describes the results of experiments performed on guinea-pigs by the injection of pure cultures of the diphtheria bacillus, and by mixed injections containing also streptococcus, staphylococcus, and pneumococcus. Dr. More Madden of Dublin writes (in English) on the Hygiene of Childhood, and Dr. Ducl of Milan on the Influence of School-life on the Eyesight. Professor H. Manley of New York has a long paper on Early Operations for Harelip, illustrated with characteristic photo-engravings. Drs. Moore and Sierra of Santiago state that in Chili the death rate of children under seven years of age is 474 per mille, and that for 663 legitimate births there are 343 illegitimate. Drs. P. Celoni and L. Sacchi of Florence report Three Cases of Successful Surgical Treatment of Tuberculous Peritonitis in Children of five and seven years of age. In the Pharmacological section, Professor Fraser of Edinburgh has articles on Bichromate of Potassium as a Remedy in Gastric Affections, and on the Treatment of Myxoedema with Thyroid Gland. Dr. Lauder Brunton describes an Instrument for maintaining Artificial Respiration for a long time, and Dr. John Gordon of Aberdeen adds a contribution to the study of Piperazine. Professor Rajmondi and Dr. Rossi of Siena give the results of Observations on Poisoning by Coal-gas. Drs. C. Falcone and L. D'Amore of Naples state that long-continued small doses of phosphorus cause diffuse parenchymatous nephritis and fatty degeneration of the liver. In the section of Medicine there is an elaborate paper by Dr. N. Pane of Naples on the Immunisation of Rabbits against the Virus of Anthrax and Pneumonia, and a similarly important one by Professor R. Feletti of Catania on the Febrile Process Excited by

Laveran's Microbe of Malaria. Dr. M. Delneau of Paris writes on the Resuscitation of Asphyxiated Persons by forcible, rhythmic, alternate traction and releasing of the tongue fifteen or twenty times per minute, corresponding to the rate of the respiratory movements. Dr. Fenton B. Turck of Chicago, having found that the mucus adherent to the stomach in chronic glandular gastritis is not removed by lavage, has devised a sponge swab mounted on a braided wire and caused to revolve within the stomach so as to cleanse it effectually. In his paper, which is in English, he mentions that of 123 cases treated by this method 90 were cured in from four to eight weeks. Professor Fraser of Edinburgh, writing in English, gives details of his treatment of Pernicious Anemia with Bone-marrow; Professor Stokvis of Amsterdam writes on the presence of Hematoporphyrin in Urines absolutely free from actual blood, recommending Garrod's method of collecting it by precipitation along with the earthy phosphates thrown down on the addition of caustic potash; Professor Guido Baccelli of Rome, Italian Minister of Public Instruction and President of the Congress, has an important and suggestive paper on the Vaso-motor Apparatus of the Heart and the Diagnosis of Heart-Disease; he also contributes articles on Malaria and on the treatment of obstinate cases of Syphilis by means of intravenous injections of a solution containing one part of corrosive sublimate and three parts of chloride of sodium per 1000.

Several of the memoirs contained in these volumes were, immediately after delivery, published in THE LANCET of April 7th and 14th, 1894, such as those by Sir Dyce Duckworth on the Rheumatic Nature of Chorea (which now appears in Italian), by Professor Lindsay Steven of Glasgow on Pancreatic Hemorrhage and Necrosis, by Dr. Calmette of Paris on the Immunisation of Animals against Snake-bites, by Professor Guarneri of Pisa on the Germ of Small-pox, &c. The forthcoming volumes of these proceedings, dealing with Surgery, Obstetrics, Dermatology, Syphilography, &c., will be awaited with much interest.

MAGAZINES.

Science Progress. Vol. III., No. 15, May, 1895.—To the medical profession the most attractive articles in this number are that by Dr. Augustus D. Waller on Two Fundamental "Laws" of Nerve Action in Relation to the Modern Nerve Cell, and that—which is an excellent *résumé* of the subject—on the Antitoxins of Diphtheria by Dr. G. A. Buckmaster of St. George's Hospital. In addition, Professor Oliver Lodge contributes Light and Electrification; Alfred Harker, M.A., Methods of Petrographical Research; J. W. Rodger, A.R.C.S., Progress in Physical Chemistry during 1894; George Murray, F.L.S., Notes on the Reproductive Organs of Olive-brown Seaweeds; and W. Garstang, M.A., a Note on Budding in Tunicata—all of which, in accordance with the traditions of the journal, are severely scientific. The appendices contain a few short notices of books and the usual "enumeration of titles of chemical papers appearing in March, 1895." Why *chemical* papers only, it may be asked, in "a monthly review of current scientific investigation"?

Chapman's Magazine.—The June number of this periodical is an improvement in sundry ways over the first issue. The pages are cut, there are no inset advertisements, while the contents show a fairer proportion of narrative form to dialogue. The latter is a tempting form of composition, but requires to be exceedingly well done. Mr. George Glasing contributes one of his powerful and lurid studies of lower middle-class life, dealing this time with religious mania. The Microbe of Pessimism is a clever sketch by an "unknown writer," from whom we hope to hear more. In the Rousing of Eve Garland Mr. Richard Pryce gives a carefully studied picture of the curious way in which pathos and comedy

are blended in the human mind. The two serials by Mr. Bret Harte and Miss Violet Hunt are going well. The latter is one of the few writers who can handle dialogue form with success and safety. She always knows how far to go, and paints the individuality of her characters very forcibly with extraordinarily few touches.

The Journal of Physiology. Edited by MICHAEL FOSTER, M.D., F.R.S., and J. N. LANGLEY, M.A., F.R.S. Vol. XVIII. Nos. 1 and 2. London: C. J. Clay and Sons. May 20th, 1895.—The articles contained in this part are six in number—namely: 1. Vaughan Harley: the Normal Absorption of Fat and the Effect of the Extirpation of the Pancreas on it (we have referred to this article in another column). 2. Leonard Hill: the Influence of the Force of Gravity on the Circulation of the Blood, with twenty-five figures in the text. 3. J. W. Pickering: Synthesised Colloids and Coagulation. 4. J. N. Langley and H. K. Anderson: on the Innervation of the Pelvic and adjoining Viscera; Part I., the Lower Portion of the Intestine. 5. J. B. Leathes and Ernest H. Starling: on the Absorption of Salt Solution from the Pleural Cavities. 6. J. Burdon Sanderson: the Electrical Response to Stimulation of Muscle and its relation to the Mechanical Response, with four plates and thirteen figures in the text.

New Inventions.

THE YALE SURGEON'S CHAIR AND THE GOULD DENTAL CHAIR.

We give below illustrations of these two new and elaborate chairs, the invention of the Canton Surgical and Dental Chair Company, of Canton, Ohio, U.S.A. The Yale Surgeon's Chair is in appearance, when none of its numerous movements are being employed, an ordinary arm-chair, only the rather portentous pedals and levers about the base suggesting for it any further purpose than to sit in, for the head-rest is adjustable, not fixed; but by simple arrangement of racks and levers its component parts can be made to assume various angles with and planes towards each other, so that the body of the patient, following the various shapes of the chair, will assume any attitude that could be desired by physician, surgeon, or gynaecologist. The illustration shows the

FIG. 1.

The Surgeon's Chair as a three-quarter length operating table.

chair in the position called "the three-quarter length operating table," and it will be seen at a glance that by elevating the back it would become a suitable chair for eye operations, while by raising the leg-rest it is transformed into a full-length operating table. Such a full-length couch can also be made by pedal movements to rise on its legs to any reasonable height to suit the convenience of the surgeon, and will also rotate through the vertical plane, so that the head of the patient can be raised or depressed at will. The head-rest, is provided with a peculiarly constructed universal joint

which can be solidly locked by the turn of a single screw. The arm-rest is capable of being placed in various positions either for operating purposes, to economise space, or in cases of operations on the throat or eye as a seat for the surgeon. A special head-rest for ophthalmic work forms an additional and useful attachment.

The Gould Dental Chair, like the chair previously described, has pedal and lever movements by which it can be made to assume any necessary shape that will enable the dentist to treat his patient most conveniently. It is provided with a

FIG. 2.

The Gould Dental Chair.

lateral oblique movement, so that the body can be thrown obliquely towards or from the operator, while it can be raised, lowered, and rotated on its pedestal. It is provided with an adjustable back moving through a range of seven inches, so that it can be made to form a well-fitting seat for patients of all sizes.

These two chairs are decidedly ingenious of construction, and, having regard to their highly finished workmanship, cannot be considered expensive, costing from £15 to £20 according to the material in which they are upholstered. The Approved Novelties Company, 91, Queen-street, Cheapside, are the English agents of the Yale Surgeon's Chair and the Gould Dental Chair.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—

The nineteenth annual meeting of the British Medical Temperance Association was held on May 28th at the Holborn Restaurant, under the Presidency of Sir B. W. Richardson. The hon. secretary, Dr. Ridge (Enfield), read the annual report, showing 29 new members during the past year and 3 student associates, making altogether 411 members, 55 student associates, and three associates. It was announced that the examiner, Dr. Barlow, had awarded the first prize of £5, offered for the best essay by medical students in their third year on the Arguments derivable from Physiology for Total Abstinence from Intoxicating Liquors, to Miss M. Stewart of the London School of Medicine for Women; no essay had been deemed worthy of the second and third prizes. More than 15,000 copies of the *Medical Pioneer*, the organ of the association, had been sent gratuitously to medical men, hospitals, &c. The constitution was then amended, so as no longer to require subscriptions from student associates. After the usual votes of thanks the meeting was concluded, and several members and friends dined together at the Restaurant.

THE LANCET.

LONDON: SATURDAY, JUNE 8, 1895.

SUNDAY, June 16th, is the day selected this year for the simultaneous appeal from London pulpits on behalf of the medical charities of the metropolis. For two-and-twenty years this annual appeal has gone forth, and the people of this great and wealthy community have been asked to spare, in the midst of the pleasures and attractions of the season, a few thoughts for the needs of the sick poor and to bestow some contribution in money towards the support of those institutions whose glory is that they are "maintained by voluntary contributions." The Hospital Sunday Fund has during its existence done much to regulate the great charities for whose assistance it was founded. In the bestowal of the sum entrusted to them for distribution the members of the committee of the Fund, presided over by the Lord Mayor of London, have endeavoured to be guided by the strictest impartiality, and have performed their philanthropic duty with justice and discretion. The share taken by THE LANCET in the institution of this annual collection from every religious community, and in particular the devoted and practical sympathy which, while he lived, its then Editor, the late Dr. JAMES WAKLEY, evinced on behalf of the Fund, are well known, and we have endeavoured to continue in each succeeding year to help its work on definite lines. It has been our main object to assist those who plead the cause of the hospitals with persuasive eloquence, by preparing for distribution among their congregations a summary of the objects of the Fund and of the needs of the hospitals. If in so doing we may be thought to have diverged in any degree from the objects of a medical journal, we can only say that the cause of charity knows no limitations, and that we claim no recognition for the performance of a task which we regard as at once a duty and a pleasure. For once, then, in the pages of the Supplement which it has now been our custom to issue on this day for many years, we address a wider audience than is our wont and do our best to arouse our fellow citizens to a sense of the claims that their less prosperous fellow men have on their thoughts and sympathy. The medical profession is daily, nay hourly, engaged in this devoted service of man. Those only can speak of the amount of its devotion to this cause who are of it, and who have followed it into the by-ways of misery which abound in this huge and densely crowded city. As medical journalists, then, we feel that we have a right to ask that some small share of the burden should be borne by others whose sole opportunity, perchance, of joining in this gracious service is limited to a response to the appeal from the pulpit on Hospital Sunday.

In order that no member of the congregations which will be invited next Sunday to contribute to the Hospital Sunday Fund may plead ignorance of the work done by the hospitals as a pretext for complying with the request for aid in the letter rather than in the spirit, we have devoted the whole

of this year's Supplement (125,000 copies of which will be gratuitously distributed throughout the congregations to-morrow), apart from the statistical tables, which tell their own tale, to a brief description of the machinery by which the benefits of skilled medical and surgical attention are brought within the reach of those who are prevented by fate or misfortune from obtaining them by payment. These details, trite and familiar to the members of our profession, will, we venture to think, come as a revelation to a large number of those who are asked to contribute to the Sunday Fund. It would have been easy to have amplified the account in many respects, but so far as it goes it cannot fail to show that the organisation of a hospital demands the energies of a large number of persons and the co-operation of many minds trained for the most differing pursuits. Then, too, it must be borne in mind that much of this labour—in truth, the chief part of it—is given willingly without return; whilst of that for which there is remuneration this latter is singularly small compared to the rewards to be gained in other walks of life. It is, we know, often urged that an appointment to a position on the honorary staff of a public hospital brings its reward indirectly in reputation and in consulting practice. This may be so, and in some conspicuous instances it is patent; but we have no hesitation at all in declaring that the hospital physician or surgeon does not necessarily reap such benefit, even after long years of unselfish service. If only the contributions of the laity could in the very smallest degree approximate to the value of the services rendered by a hospital staff within one single year there would be no more heard of the poverty of these institutions.

The conscience of London has not yet been thoroughly aroused upon this question of hospital relief. Year by year this great city grows greater; year by year it grows wealthier; year by year the claims on charity grow more urgent and more needful. How are these claims being met? How is the Londoner to be made aware of his high responsibilities, we might say of his great privileges? It is surely something to belong to the metropolis of the world, but it is better to prove that this citizenship is no mere name. Once in every year he has afforded him the opportunity of proving that he is worthy to be on the roll of this vast community. Once every year the power is given him of proving that he is not insensible to the suffering that surrounds him on all sides. Surely if London—Greater London—desires to prove to the world that she can be stirred by a common impulse, it would be on an occasion such as this, which is afforded by the institution of Hospital Sunday. It is fitting that this cause should be interwoven with religion, for the sum and substance of all religion is to succour the poor and needy, to love one's neighbour as oneself. But whether a man profess his religion openly, under one of its many forms, or whether he prefer to follow the dictates of his own conscience, it matters not. To one and all the lesson of Hospital Sunday must be taken to heart, the lesson of self-sacrifice which is as ancient as humanity itself and is the crowning glory of mankind. With such a theme we might be tempted to pass beyond our proper sphere, but it is with those whose office

It is to kindle consciences that the duty lies. We must be content to affirm that London has not yet in any one year since the Metropolitan Hospital Sunday Fund was started made such a contribution as is at all proportionate to her wealth or population. May she redeem herself from this reproach next week by providing a sum of at least £50,000.

To all those who take an interest in our water-supply the note sent out from the Surgeon-General's Office of the United States War Department, Washington, will convey an idea of the great importance that is nowadays attached to the bacteriological examination of water by State and municipal authorities who are not too firmly bound down by tradition to ancient methods of procedure and inactivity. The Committee on Water Pollution of the American Public Health Association, in a report presented at a meeting of the Association held at Montreal in 1894, in this note strongly recommends coöperative work in the study of bacterial forms in water as bearing on scientific questions. The Chairman of the Committee, Major and Surgeon CHARLES SMART, U.S. Army, writes: "This was approved, and the Committee is now organising the laboratories of the United States and Canada in the investigation. A subcommittee on methods of laboratory work was appointed. The subcommittee considered that by getting in detail accounts of the methods in use in the various laboratories, consolidating these, and submitting the resulting scheme to an advisory council of the prominent bacteriologists in America, it would then be able to proceed with coöperative work in the study of the bacteria of water." Certain difficulties have arisen, but so much progress has been made that a special meeting of bacteriologists, at which the following questions are to be discussed, has been called for this month (June): the differentiation of species and the production of varieties which may arise—(1) from differences in environment in nature, and (2) from divergent conditions in laboratory methods. With regard to the former, it is evident that the conditions under which these occur or are produced can be but little controlled by the investigator; but in respect to the second heading, it is evident that by combined work, carried on under a common system, the varieties produced in this way may be greatly diminished or, at any rate, reduced to uniformity; whilst, as the report points out, it is evident that the first-named varieties cannot be satisfactorily studied until control has been obtained over the latter. The circular letter which has been sent to all the bacteriologists in America insists that more accuracy must necessarily be gained if the data under the four headings following are thoroughly understood: (1) the due recognition of the great importance of the reaction of culture media; (2) the variability of the composition of media exclusive of acid or alkaline; (3) the divergencies of conditions for development other than media in published reports on the bacteriology of water; and (4) the imperfectly systematised records of the results of cultivation experiments. In order to facilitate discussion and to allow of the evidence being readily classified the committee, consisting of four members, with Dr. J. G. ADAMI as secretary, submits the following points as amongst the most important for consideration:—

1. What methods shall be followed in neutralising all

- media, and what standard degree of reaction shall be adopted? 2. What effects upon species differentiation are produced by ordinary differences in composition of peptone, meat juice, gelatine, &c.? 3. What media shall be used for all species differentiation, and how shall they be uniformly prepared? 4. What shall be the medium for, and the conditions of, the stock culture from which all media are seeded? 5. What shall be the systematic detailed method to be followed in observing the results of cultivations and the manner of recording them? 6. What method shall be adopted by which full benefit may be derived from morphological characteristics? 7. What tests shall be used for separating bacteria into clearly marked groups? 8. What shall be the method followed in determining the relation of bacteria to temperature? 9. What special methods are of value in the isolation of pathogenic bacteria in water? 10. What shall be the method of procedure in determining the pathogenesis of bacteria found in water? 11. What evidence is there at hand with regard to the variability of species? 12. What new methods can be suggested for the separation of bacteria into groups and for the identification of species?

As the question must necessarily be raised in connexion with the examination of the London water-supply, in view of suggested changes, these points should be carefully studied. A slight attempt has been made by the Water Research Committee of the Royal Society, aided by a grant from the London County Council, to clear up some of the questions involved in such an investigation, but the fringe of the subject has only been touched, and the published work, both by what it contains and by what it has been unable to achieve, gives evidence of the enormous amount of work still to be done and of the great necessity there is for a combined investigation on an extensive scale.

At last week's meeting of the Liverpool Health Committee the question of the employment of female sanitary inspectors came up for discussion on the report of the medical officer of health. It appears that the Ladies' Health Society of Liverpool had recently addressed to the corporation a request that a certain number of properly trained female sanitary officers should be employed in that city for the discharge of those duties to the female portion of the community which cannot with decency be carried out by inspectors of the opposite sex. The question is in many respects an important one, and should be carefully discussed in all its bearings; we are therefore glad to note that it has been decided to encourage further conference with regard to the matter between the Ladies' Health Society and the administrative departments of the corporation. At the committee meeting above mentioned it was agreed that the employment of women for the execution of sanitary functions was an untried experiment, and several members expressed the opinion that such appointments were open to grave administrative objections. As regards the experimental nature of the scheme, however, it may be mentioned that at least one of the London vestries has already appointed a female sanitary inspector; and although the women employed by the Ladies' Health Society of Manchester are not specifically designated sanitary inspectors we nevertheless find, from the weekly health reports of that city, that they discharge functions

which in their nature are distinctively sanitary. The contention of certain of the Liverpool councillors is doubtless valid—viz., that many of the duties under the Public Health Acts which devolve upon sanitary inspectors are arduous and sometimes dangerous, and are therefore such as women are physically unfit to undertake. But, on the other hand, it may surely be urged that many of the most important of the duties under the Acts not only can but obviously ought to be performed by females only. For example, the routine of what is known as sanitary inspection constantly involves entry by the inspector into private dwelling-houses, and as such visits have frequently to be made to females or children whilst suffering from illness and in bed it is obviously fitting that they should take place under conditions which do not tend to diminish those feelings of propriety and self-respect which it should be our object to encourage amongst the wives and daughters of the labouring classes. In case of childbirth, and especially on the supervision of puerperal complications, domiciliary visits by sanitary officials are often urgently necessary. It is intolerable that services which, under these circumstances, we know to be essential to life should be performed otherwise than by medical practitioners or by those whose sex specially fits them for the task.

The experiment of sanitary inspection by female agency, although perhaps technically novel, has nevertheless virtually passed beyond the experimental stage in other towns besides Manchester. In Salford and in Glasgow the same practice obtains, and in the latter city we believe that the employment of female officers for the visitation of the sick poor and for certain other sanitary purposes has long been in vogue, and as the practice is still continued under such able sanction as that of Dr. J. B. RUSSELL we may rest assured that the plan is a success. We find from the local press that Liverpool was the first English city to employ successfully a woman as a School Board officer, and should the sanitary authorities of that city decide to appoint tentatively a sufficient number of female officers for the execution of certain kinds of sanitary work amongst the poor it is not improbable that the result will be equally satisfactory.

Soon after the promulgation of the recommendations formulated by the Association of Fellows, which were detailed in our leading article on the Royal College of Surgeons of England in our issue of last week, a second body of Fellows sprang into existence and took the name of the Society of Fellows. Its scope and objects differed essentially from those of the Association of Fellows, and consisted not in originating reforms, but in submitting propositions put forward by others to the Fellows of the College for the purpose of ascertaining to which side the preponderance of opinion inclined. This may be gathered from the first resolution passed at the meeting held on April 5th, 1894: "That in view of the two annual meetings of Fellows now arranged for by the Council a Society of Fellows of the Royal College of Surgeons of England be forthwith formed with the object of ascertaining by conference and otherwise the opinion of the general body of Fellows on any subjects which may properly be brought forward at the official meetings of the Fellows

of the College and of presenting them thereto to the Council; and, in addition, of taking such steps as from time to time may seem best calculated to promote the interests of the College." Three points were submitted to the Fellows in May, 1894: the amendment of By-law XVI., to deal more effectively with the misconduct of Fellows and Members; the mode of election of the President; and the constitution of the Court of Examiners. With the first of these questions the Council had already dealt, whilst the third has aroused but little interest amongst the Fellows generally.

The solution of the second question—the question of the best method of proceeding to elect the President—has been advanced a stage by the action of the Society, the result of a preliminary canvass inducing the executive of the Society to submit the following resolution to the meeting of Fellows held on July 5th, 1894: "That the Council be requested to take steps for obtaining the opinion of the Fellows on the mode of election to the office of President." This resolution was carried by 23 votes to 8, and was considered by the Council of the College at the quarterly meeting held on July 12th. Mr. BRYANT then moved, and Sir SPENCER WELLS seconded, the following resolution: "That the Council of the College are not prepared at the present time to consult the Fellows or solicit their opinion through other means than the meetings of Fellows which have been lately established." An amendment, proposed by Mr. RIVINGTON and seconded by Mr. WILLETT, "That, in compliance with the request of the meeting of the Fellows on the 5th inst., the Council do take steps for obtaining the opinion of the Fellows on the mode of election to the office of President," was lost, and the original motion carried, with the following addendum: "The Council would, however, point out that if any Fellow is anxious to test the opinion of the general body of Fellows as to whether or not it is desirable to make any change in the present mode of election to the office of President it is open to him to do so by submitting a motion on the question to the meeting of Fellows in January or to some subsequent meeting." The outcome of this decision was a conference between the Association of Fellows and the Society of Fellows, at which it was agreed that the canvass of the Fellows generally should be undertaken by the Society of Fellows. This canvass was carried into effect, and, so far as it went, resulted in showing that nearly two-thirds of the Fellows who replied desired that the President should be elected by the Fellows either directly or after nomination by the Council.

For the time being the question of the mode of election of the President of the College has become of secondary importance, or rather a matter of detail in connexion with the larger question of obtaining a new Charter. We have for some time contended that the concessions granted by the Council both to the Fellows and Members ought not to rest merely on resolutions and regulations of the Council which are subject to revision or revocation at the good pleasure of the Council, and leave the Fellows and Members to hold their new privileges on sufferance only. This view has also been taken by the Association of Fellows, on whose behalf a resolution was proposed at the half-yearly meeting of Fellows held at the College

on July 5th, 1894, to the effect "that, in the opinion of this meeting, the concessions made by the Council, and such other changes as the general body of Fellows may desire, should be embodied in a new Charter." In a small meeting, however, an amendment was carried "that it is premature to consider the question of a new Charter until the changes required have been resolved upon." In the course of the discussion it was suggested that the best mode of procedure would be to form a conjoint committee of members of the Council and other Fellows of the College to consider the whole question, and such a resolution would have been carried (instead of the amendment passed at the meeting) but that it was ruled by the President that notice of a motion involving a new departure ought to be given. Under these circumstances the discussion of the proposal had to be adjourned to the meeting of Fellows in January, 1895, when, with the support both of the Association of Fellows and the Society of Fellows, the following resolution was adopted: "That the Council be requested to appoint a conjoint committee of members of the Council and Fellows of the College to consider the desirability of obtaining a new Charter, together with the details thereof."

On referring the question of the appointment of such a committee to the legal adviser of the College the Council was informed that it would not be illegal to obtain "the advice of such a committee or of any other body they might think fit to consult," but that "such a committee could have no official character and could do no act or pass any resolution that would have any binding effect whatever; and, indeed, its proceedings would have no more legal effect than that of any outside body whom the Council might think fit to consult. Such a course, though not illegal, would be calculated to give rise in the future to legal complications, as the purely non-official character of the committee would in course of time be liable to be overlooked." On the other hand, "a committee of the Council to meet and confer with a deputation of Fellows would meet the desired object without giving rise to any such complications as those referred to."

The result was that at the meeting of the Council held on Feb. 7th the Council "did not deem it expedient to accede to the resolution passed at the meeting of Fellows held on the 3rd ultimo"; and further resolved "that a committee of the Council be appointed to receive deputations from the Fellows of the College upon the subject of the resolution of the meeting of Fellows on Jan. 3rd last, and to report thereon to the Council." It was also resolved that "copies of the two foregoing resolutions be forwarded to the mover and seconder of the resolution of the meeting of Fellows." The Council then appointed "Mr. BRYANT, Mr. HOWSE, Mr. RIVINGTON, Mr. TWEEDY, and Mr. MORRIS, together with the President and Vice-Presidents, members of the committee to receive the deputations." The sudden and lamented death of the late President, Mr. HULKE, entirely prevented any action being taken to give effect to the foregoing resolutions, but we understand that a request for the reception of a deputation by the committee has been sent to the secretary of the College on behalf of the Association of Fellows, and that the President of the College has appointed Monday, June 10th, for the reception of the deputation. It is not improbable that the Society of Fellows will

also send a deputation to the committee, and it ought to be understood by the Fellows of the College that it is open both to metropolitan and to provincial Fellows individually to apply to be received by the committee. The Association of Fellows intends, we believe, to adopt the recommendations which it promulgated some time ago as the basis for its suggestions, and we trust that other bodies of Fellows who have definite propositions to make will not fail to utilise the favourable opportunity which is now presented for the furtherance of substantial reforms in the constitution of the College.

Annotations.

"Ne quid nimis."

MEDICAL CERTIFICATES FOR THE LONDON BOARD SCHOOLS.

WE have already had occasion to comment upon the appalling ignorance of the laws which govern the conduct of medical men towards one another displayed by a certain London vestry, but that was a local matter. A danger affecting the honour of the medical profession throughout the metropolis has now arisen, and the exciting cause is that association of servants of the ratepayers known as the London School Board. At the debate on Thursday, May 30th, Mr. Sharp, chairman of the School Attendance Committee, moved:—

"That the West Lambeth Divisional Committee be authorised to appoint for one year, upon the under-mentioned conditions, six doctors in that division to examine cases in which the medical certificate produced is considered by the divisional superintendent to be doubtful, or in which it is desirable to have a definite medical opinion. (a) That each case be first referred to the divisional member in charge of the school where the child ought to attend. (b) That a payment of 2s. 6d. shall be made for each case examined. (c) That the number of cases to be dealt with in this manner shall not exceed 100 in the year. (d) That the names of the doctors selected shall be forwarded to the magistrates having jurisdiction in the division."

He explained that in view of the favourable result of the experiment tried in the Tower Hamlets Division the committee were of opinion that the plan should be adopted in the West Lambeth Division, the divisional superintendent having recommended that course. Mr. Athelstan Riley moved as an amendment to strike out all words after "produced" in the first paragraph and to insert "is not signed by a properly qualified medical man." Mr. Riley's very sensible amendment was negatived by 26 to 20, and the recommendation of the committee was carried by 26 votes to 18. Let us now examine the scheme of the Board more in detail. It is quite evident that it has a profound distrust of (1) the parents of children, and (2) of the medical men whom they employ. Besides this, the person who is to decide upon the validity or accuracy of the certificate is not the Board's medical officer or any other medical man, but the divisional superintendent, and what qualifications can he possibly have for deciding these points? A Mr. Macnamara said he knew of "a place where they could get pretty nearly as many certificates as they liked for a penny—at a medical mission." We would ask him if by this remark he meant that certificates were granted on other than sufficient grounds for the price of a penny? If he did not mean this there is no point in the remark, for out-patient physicians or surgeons, to say nothing of house physicians and surgeons, are constantly signing certificates for nothing. We protest in the strongest manner against the proposition of the Board; it is a deliberate and wanton insult to the members of the profession. To supervise certificates which are signed by

unqualified practitioners, herbalists, &c. is quite right, but that the guarantee of a properly qualified man should be called in question by a divisional superintendent is unwarrantable. Nor do we believe that six medical men will be found to sit in judgment upon another practitioner's certificate. The Board, like other corporate bodies, has neither a soul to be saved nor a body to be kicked, so it is hard to influence; but if it persists in its present course the only result will be that no medical man will sign School Board certificates at all—the parents will be summoned, the medical man in question will give evidence, and the charge will be dismissed. If the Board thinks that this course of action will enhance its popularity with either parents or ratepayers, let it go on. If not, we advise it to treat the profession with the courtesy we have a right to demand. We believe the orthodox manner of bringing outside opinion to bear upon the Board is by means of a deputation, and we would point out to the profession that in this manner the gross breach of etiquette which the Board has committed may be pointed out to it. A deputation of representative medical men would be able to lay a mass of evidence of great weight before the Board, and to such members of the profession we commend this idea.

"HE WANTED TO KNOW, YOU KNOW."

MR. OLIVER PEMBERTON, the city coroner at Birmingham, has been emulating Mr. Clennam, who "wanted to know, you know," and has received a remarkable proof of the fact that among certain of our public bodies the habits and traditions of the Circumlocution Office still linger. Mr. Pemberton held an inquest on the last day of May upon the body of one Albert James Grimshaw, who was stabbed and who died at the Birmingham General Hospital from the injuries he had received. A man named John Saunders was taken into custody by the Aston police and charged with causing the death of Grimshaw. It is clear that the inquest may possibly result in a verdict of wilful murder against the arrested man, for which reason Mr. Pemberton very properly and fairly desired that Saunders should have an opportunity of appearing at the coroner's court if he chose to avail himself of it. And now begins the game of circumlocution. The Aston magistrates appear not to have desired to sanction the presence of Saunders at the inquest. Mr. Pemberton wrote to the clerk to the magistrates to ask that Saunders should be permitted to come before him if he wished to do so, and in return received a reply stating that the magistrates had no power to direct the police to take the prisoner to the coroner's court. Mr. Pemberton then applied for assistance to the superintendent of police at Aston, begging him to deal with the matter, but the superintendent said that it was out of his jurisdiction. Mr. Pemberton next wrote to the governor of the gaol where the prisoner was in custody, and from him (Admiral Tinkler) received a formal communication that the prisoner desired to be present at the inquest, the governor also promising to write to the Commissioners of Prisons to ask for orders to produce Saunders at the coroner's court. Now, what all this circumlocution may mean, who is served by it, and which of our national liberties is safeguarded by it does not lie very near the surface, but what is abundantly clear is that gross injustice may be done to the man Saunders by withholding from him the opportunity of appearing to listen to, and if necessary refute or attempt to refute, the serious charges that may be made against him in the coroner's court. Mr. Pemberton's action in being determined to find out why the doing of such an obvious act of justice was beyond the powers of three different sets of officials and required the sanction of the highest authorities after an interval of ten days' thought is commendable; certainly any public official who brings to light these irritating flaws in our social

economy is also a public benefactor inasmuch as he has spared himself no trouble to obtain justice for a man over whose head the most serious charge known to the law is impending. Could not Mr. Pemberton have succeeded in obtaining the presence of Saunders by application to the Home Office in the first instance? We think it probable that by this means the desired result would have been attained.

CREMATION ON THE BATTLEFIELD.

WHEN the great surgeon Billroth, elected to the Austrian Upper Chamber, made his memorable speech for the rehabilitation of the Medico-Military Academy of Vienna, he pointed out some of the inevitable incidents of modern as contrasted with past warfare, which would make the educative function of such an academy more than ever indispensable. The advance of military science, he showed, with its arms of precision and its smokeless powder, would so encumber the battlefield with wounded that the transport service, hitherto available for the removal of these to the rear, would have to be greatly improved in promptitude and efficiency if the combatant arm was not itself to be paralysed by its own fallen encumbering the ground. To this admonition the International Red Cross responded nobly, and the exposition of the various modes of picking up and carrying off the wounded which were on view at Rome during the last great Medical Congress satisfied the medico-military world that, if not absolutely solved, the problem of carrying the wounded to the rear was on the high road to solution. But the dead on the battlefield offer as difficult a *crux* for the army medical or the Red Cross organisation to deal with as the dying. How are they to be disposed of after those of the fallen who may yet be saved are happily put under treatment in the field ambulance? Not for the first time has the question been propounded to the War Departments of the European Powers. The other day the Emperor William, in view of the carnage inseparable from latter-day warfare, took counsel with the medical staff of the German War Office as to whether, or to what extent, cremation might not be utilised for the disencumbering of battlefields after such sanguinary combats as those, for example, around Metz in the campaign of 1870. The subject is full of difficulty, and even if cremation be eventually put in practice for such an end it must, without question, call into operation a much larger, a much more variously disciplined medico-military personnel than hitherto. The electric light, after darkness has set in, may be trusted to aid in distinguishing the dying from the dead; but expert examination will be needed before such an irrevocable process as that of the crematorium is applied to bodies in which the vital spark, not wholly extinguished, may yet have a chance of being fanned into flame. This examination will not be called for in the case of those who are either killed outright or whose condition is such that only a few minutes can intervene before rigor mortis begins to declare itself. It may be spared also in those cases where after operation the resources of the field ambulance have failed to reinforce the powers of life. But from the two sides of the battlefield—from the front and from the rear—the crematorium will never be without food, all too abundant, if the provisions of the Emperor William as to the "butcher's bill" of the next great European war are to be realised. The subject, as we have said, is not now for the first time propounded. In the great International Congress for the Relief of the Wounded in War, held in Paris twenty-eight years ago, Dr. Bertani, the distinguished Genoese surgeon, who sacrificed a brilliant academic career and a rapidly extending private *clientèle* to organise the medico-military department of Garibaldi's campaigns, proposed cremation as the humanest and, from the hygienic point of view, the soundest

modus operandi to be employed in the disposal of the dead on the battlefield. His proposal was ably seconded by another sagacious Italian sanitarian, Dr. Castiglioni—seconded, moreover, by arguments so powerful that nothing but the short interval between its recommendation and the outbreak of the Franco-German War explains its not having been put in practice during that most sanguinary of nineteenth century campaigns. The testimony of the great soldier-surgeons of Italy's struggles for independence will, however, bear revival and recapitulation, especially under the auspices of the "predominant partner" in the Triple Alliance, the Emperor William, whose capabilities in the art of war are not more conspicuous than his wise provisions for the abatement of its horrors, and whose steady patronage of all that pertains to the sanitary protection of his people will one day reflect as much honour on his reign as the most brilliant achievements of his ancestors in the military council-chamber or on the stricken field.

PROFESSOR BROUARDEL ON THE MEDICAL PROFESSION.

ONE of the great questions of the day undoubtedly is, What shall we do with our sons? In the profession with which we are more immediately concerned there are at the present moment close on 33,000 gentlemen with British qualifications practising the science and art of medicine in all parts of the world, but chiefly within the narrow limits of our own small islands. The plethora of *alumni* in our schools is truly alarming, and yet we have cause to congratulate ourselves that matters in this respect are not so bad with us as they are elsewhere. In the United States, for instance, the medical student roster last year was said to contain no fewer than 38,850 names, being an augmentation of more than 5500 since 1892. In France the overcrowding of the medical schools is also excessive, but in this connexion we cannot do better than quote the remarks delivered by Professor Brouardel at a recent meeting of the Association des Médecins du Département de la Seine: "Two years ago I drew your attention to the fact that the number of medical students was increasing rapidly. The augmentation still continues unabated. In all the French faculties our future *compères* are now twice as numerous as they were ten years ago. The same kind of thing is going on in Germany and likewise in England. Various causes have been invoked in explanation of this state of affairs; many people thought that the law regulating military service was to blame in the matter. There is no reason whatever for this supposition. The laws have not been altered in Germany or in England, and yet the rate of progression remains the same. In France the female midwifery candidates, who have nothing to do with military service, have doubled their numbers in the last five years. For my part I am convinced that it is the publicity accorded to the achievements of science which is responsible for the illusory ideas entertained by heads of families. Day by day in their newspapers they see the great importance that on all sides is attached to public health, civil and military, and logically enough imagine that the persons charged with the solution of the great problems involved receive a proportionate compensation. They conclude that their offspring will derive both honour and profit while pursuing this grand career. They would be much astonished if anyone were to point out how the efforts we make to render houses wholesome, to root out epidemics, to improve medical charities, all have the effect of narrowing more and more the field wherein the medical man was formerly wont to garner a meagre harvest. Now, in ten years' time the number of reapers will have doubled. I do not want to forecast the consequences from the point of view of medical practice, but there is one thing of which we may be perfectly sure: if the number

of medical men has doubled, the number of unsuccessful practitioners will have increased threefold." The eminent French sanitarian doubtless correctly estimates the motives that induce his fellow countrymen to enter their sons in medicine. All communities are alike and, although many-headed, are not endowed with a corresponding amount of intelligence. And yet it is difficult to conceive how any reasoning being can suppose that the average medical man's life is either an easy or a lucrative one. There is no other profession or calling in which the hours are so long. A busy practitioner (and if he has to live by his labour he is compelled to be busy) must remain on duty twenty-four hours out of the twenty-four. At no period of the day does the happy moment arrive when he can put his business on one side and say, "Now I may enjoy myself." Professor Brouardel's remarks regarding the way medical men cut the ground from under their own feet, as it were, by their persistent endeavours to improve the sanitary condition and general health of the community are very pertinent and should be widely disseminated. In no other walk of life do we hear of men who, as a matter of course and without the smallest fuss, are ready and willing to act in a manner that is diametrically opposed to their pecuniary interests.

STREET NOISES.

"SATED with home, of wife and children tired,
The restless soul is driven abroad to roam."

So say "Rejected Addresses," but if Mr. Vaughan's decision at Bow-street on Tuesday holds good the restless soul will be driven abroad by something worse. Three youths were charged with playing an organ to the annoyance of Mr. Kent, a hotel proprietor. He naturally enough requested them to go away, and when (as is the custom of organ fiends) they refused he called a policeman and gave them into custody. Mr. Vaughan delivered himself as follows: "Unless you are disturbed in your business, or there is sickness in the house, or your health is affected by the sounds of the organ you cannot interfere." If this be the case we can only say the sooner the law is altered the better. It is absolutely intolerable that any lazy, hulking lout should have the power to annoy his fellow creatures simply for the purpose of getting money. That organs are a source of pleasure to poor children we do not deny, and we would be the last to deprive them of it, but any householder ought to have the power of ordering an organ to be removed, not merely from the front of his house, but out of hearing, say half a mile away. If the organ-grinder should refuse he should at once be given into custody and dealt with by the law.

THE NORMAL ABSORPTION OF FAT AND THE RELATION OF THE PANCREAS TO ABSORPTION OF FAT.

DR. VAUGHAN HABLEY, in experiments made to determine the relation of the pancreas to the absorption of fat in dogs, which are recorded in the current number of the *Journal of Physiology*, pursued the following plan. The animals were kept fasting for two days and the bowels were daily washed out with an enema of hot water, a small glycerine enema being subsequently given to effect the expulsion of the water. On the third day the pancreas was removed under an anæsthetic, the enemata being continued for two days. These animals were compared with others that were intact. Each set of animals were then supplied with a measured quantity of warm milk, and after a certain number of hours, varying in different cases, the animals were killed and the entire contents of the stomach and intestines separately analysed. In the intact animals the maximum rate of absorption of fat occurs about seven hours after the ingestion of food, for normally a dog absorbs from 9 to 21 per

cent. of the total fat given in from three to four hours, from 21 to 46 per cent. in seven hours, and 86 per cent. in eighteen hours. In a normal dog the passage of fat from the stomach varies with the individual as well as with the time allowed for digestion, but in eighteen hours the whole has entered the intestines. In dogs which have had the pancreas removed the quantity of fat given is not only again recovered, but a surplus is found which is probably derived from the intestinal secretion or excretion. Dr. Vaughan Harley also found that the capability of passage of fat from the stomach is very much delayed by the extirpation of the pancreas, such dogs only passing in seven hours from 9 to 22 per cent. through the pylorus instead of, as in normal dogs, about 86 per cent.

OUT-DOOR NURSING FOR THE POOR.

A CORRESPONDENT writes to us saying that at the Hunslet board of guardians, of which he is a member, he proposed and carried a resolution to the effect that a subcommittee should be nominated to consider the appointment of a parish nurse to look after the out-door sick and infirm poor. We think this a very admirable suggestion, and cordially hope that the subcommittee in question will report favourably to their board. The importance of nursing is gradually becoming more and more realised, and the comfort of a chronically ill patient—e.g., one afflicted with emphysema or rheumatic arthritis—depends to a very great extent upon nursing. There is also the difficulty, when the mother of a family is laid up, of providing means for doing the household work, washing, cooking, &c. This necessity our correspondent proposes to meet in what we fancy is a novel manner. He wants the board to cause the able-bodied women receiving out-door relief to give one day's service per week for cleaning and washing purposes. In this way the patient's mind would be freed from the anxiety which would otherwise arise as to how the household work should be done, and so one great impediment to getting well would be removed. We have also received the report of the Affiliated Benefit Nursing Association (12, Buckingham Palace-road), which aims at supplying nurses to look after cases in remote country districts, under the supervision of a medical man. Parishes combine to support one or two nurses, the number varying according to the size of the parish, and in addition a small weekly fee is charged. In the case of our correspondent's scheme falling through he might find it useful to communicate with the association we have mentioned.

THE CORPORATION OF MANCHESTER AND MONSALL HOSPITAL.

THE treatment of infectious disease, including small-pox, in Manchester, has hitherto been carried out by the infirmary, but the question of taking up the responsibility properly devolving on it has from time to time occupied the attention of the corporation. It has been brought to the front again by the serious and prolonged visitation of small-pox from which the city has recently suffered, and negotiations have taken place between the sanitary committee of the corporation and the infirmary authorities as to the terms on which Monsall Hospital could be transferred. The original cost of the estate and buildings first erected (in 1870) was £21,400, and since that time £49,260 have been expended on additional land and buildings, so that £70,660 has been the total capital expenditure. Its gradual increase to a hospital of 380 beds has been the result of the arrangement between the two bodies. The patients have had the advantage of treatment by the honorary staff of the Royal Infirmary, assisted by highly qualified resident medical officers, and the corporation has been relieved of its obligations. The rates paid for the

patients have at times been considerably in excess of expenditure, and the "profits" have always been applied to reducing the balance of the sum of £49,260, so that on Dec. 31st last only about £17,000 remained, for which sum, as no gain is sought, the infirmary would hand over the hospital on certain conditions, the most interesting of which to our profession is that, "in view of the great public value to be derived from the teaching of medical students in the wards, facilities be given for such instruction to the students of Owens College by the honorary staff of the Royal Infirmary." The sanitary committee has also had in view the necessity for a small-pox hospital remote from population and yet sufficiently easy of access, and on May 22nd, at an adjourned discussion, the following resolutions were unanimously adopted by the city council: "1. That the sanitary committee be authorised by the council to make all arrangements necessary for the transfer of Monsall Hospital from the Manchester Royal Infirmary to the corporation upon the terms above set forth, with a view to the treatment of small-pox cases being entirely removed therefrom, and that your committee be authorised to arrange for the purchase of such adjoining land as they may deem necessary. 2. That the sanitary committee be authorised by the council to make inquiries and report as to the steps they recommend to be taken for the provision of accommodation for the treatment of small-pox cases." The chairman of the sanitary committee stated that they had in view "a very suitable site at Carrington," where the corporation has a large estate, including Carrington Moss.

THE MINERAL WATERS OF FACHINGEN.

AMONG the new claimants for attention as watering-places and health resorts is Fachingen, near the town of Diez in the department of Wiesbaden. An analysis of the mineral springs of Fachingen made by Dr. Meincke yielded the following results: in 1000 parts of water there were found to be 3.54 parts of bicarbonate of soda, 0.55 of bicarbonate of lime, 0.64 of bicarbonate of magnesia, 0.63 of chloride of sodium, and small quantities of bicarbonate of iron and bicarbonate of manganese. This amount of soda is large and exceeds that found in the principal well-known alkaline springs, with the exception of Vichy and Bilin. Of all the purely alkaline springs Fachingen is said to have the largest amount of earthy salts—chalk, manganese, &c. The free carbonic acid present in the waters amounts to 1.78 per 1000. It is claimed for these waters that they dissolve and clear away mucus from the throat or stomach, that they excite the secretion of gastric juice and promote the peristalsis of the bowels, that they increase the alkalescence of the blood, and, above all, that they materially modify the character of the urine and exercise a solvent action upon urates and uric-acid deposits. The list of affections said to be favourably influenced by the Fachingen waters is a long one. When the mouth and throat are covered with a tenacious mucous secretion the waters, especially if used warm, are efficacious in giving relief. In morning vomiting, acidity of the stomach, heartburn, acid eructations, and the like, good results follow their use. Gout is said to be favourably influenced by these waters. It is recommended that they should be taken to the extent of half a bottle or a bottle per diem in the intervals between the attacks of gout, but that their use should be suspended during the attacks. It is also claimed that the Fachingen waters are beneficial in diabetes. It is, however, in renal and vesical affections that these waters are said to possess their greatest value. In acute and subacute nephritis, catarrh of the pelvis of the kidney, uric-acid concretions of the pelvis of the kidney and of the bladder, and acute catarrh of the bladder the best results are claimed for this method of treatment. In chronic catarrh

of the bladder these waters are less applicable, but are said to be occasionally useful. We give the above particulars without pledging ourselves to the opinions expressed, but the applicability of the Fachingen waters to most of the diseased conditions specified is obvious from their chemical composition. It seems impossible to doubt that the natural mineral waters seem on the whole to succeed better than the equivalent amount of the salts which they contain. The probability is that the combinations naturally existing in many mineral waters are favourable for absorption, while the presence in some of them of large quantities of free carbonic acid renders them grateful to the palate and the stomach. It is their comparative poverty in this gas which stamps with inferiority so many of the British waters. There is one disease mentioned in the above category with regard to which we are exceedingly doubtful whether any known mineral water exercises any appreciable influence—viz., well-marked typical diabetes. That some waters—e.g., those of Carlsbad—are very useful in the glycosuria of middle-aged and elderly persons we are fully prepared to admit; but where we find typical diabetes—i.e., where thirst and wasting coexist with marked polyuria and a large excretion of sugar—we believe these waters to be practically useless, and the same remark applies to other mineral waters. To send abroad patients with fully developed and hopeless diabetes in the illusory search for mineral waters which are to accomplish what ordinary medical treatment has failed to effect is, in our judgment, not only unwise but wrong. If dietetic treatment and opium fail to arrest diabetes, no mineral water is in the least likely to do so.

"THE PREVENTION OF OVERLAYING."

WITH reference to an annotation on this subject in our issue of June 1st, a correspondent calls attention to a plan adopted by many parents to prevent their offspring from being accidentally suffocated whilst in bed. The method adopted is simply to clothe the child in flannel so that it need not necessarily depend for warmth on the ordinary bed-clothing, and then to place it high up upon a pillow laid lengthwise between the mother's pillow and the opposite side of the bed, which should be so arranged that the infant could not possibly fall out, or when the parents sleep together the infant's pillow could be placed between the pillows used by the parents. The medical attendant might easily persuade the mother to adopt this plan, and if it were done the mortality from overlaying would in all probability be considerably reduced, as if it could be shown that the mother had wilfully neglected the advice of the medical attendant she might be liable to a serious charge. In view of the fact that many mothers would consider it a great hardship to be deprived of their babies during the night the suggestion is one to which some attention might be given.

OBESITY.

To judge from daily papers the problem of "How to be happy though fat" is one which still exercises the lay mind largely, and from the same sources of information the demand appears to have created the supply, and numbers avow their readiness to give "good advice" for a consideration. Sometimes even the advice, at first sight, is more disinterested, and a charitable individual, whose name is not to be found in the Medical Directory, offers to part with the secret of his own health and happiness to anyone who will send a stamped addressed envelope, but the secret generally consists of remedies unknown to fame, even of extra-pharmacopœias and lists of recent drugs, and obtainable only, at a price, from a special source. After all, the problem is not new; it is merely a revival. Some of the methods of reducing obesity, however,

have a certain air of novelty which seems to captivate those to whom the Banting system does not appeal. None the less, however, have the warnings so frequently given in the Banting age to be repeated in these days of hot water and nitrogenous diet. There is no doubt that weight can be rapidly reduced by such measures, independently of exercise; there is equally no doubt that the rapid reduction of weight and the sudden alteration of habits for most people constitute a source of danger. Most medical men can mention instances amongst their patients of unexpected illnesses which have supervened during a course of treatment for the reduction of obesity, and in recent obituary notices references have, rightly or wrongly, been made to supposed injuries to the constitution attributable to the same cause. Doubtless, in most cases, some disease has contributed its share; but the danger of hastening latent disease, or even of reducing vitality, so that the inroads of disease are no longer successfully resisted, is one which must always be borne in mind by those who are anxious to make themselves other than they are. Obesity is often the result of errors of diet and hygienic rules; but it is not uncommonly the sequence of some constitutional condition which renders exercise a matter of difficulty or impossibility, and in such cases it is hopelessly unscientific suddenly and violently to reduce the weight.

THE WORKHOUSES OF IRELAND.

WE have received from Sir Philip Smyly, the chairman of the Irish Medical Association, and Mr. William J. Hepburn, the honorary secretary to the council of that body, the following, with a request for its publication:—

"We address this letter to you in the hope, with your powerful assistance, of enlisting the sympathy of the public with the effort now being made to reform and ameliorate the general conditions of the workhouse system in Ireland. It would be impossible in such a communication as this to go fully into the misery and wretchedness awaiting those unfortunate poor who are doomed to enter and perhaps terminate their days in some of these institutions. A circular letter asking for definite information as to the condition and wants of workhouses and workhouse infirmaries having been addressed to the medical officers, seventy-nine of those gentlemen replied, others declined, saying they feared to incur the hostility of their respective boards. On carefully examining in detail the replies of those seventy-nine we find that forty-three infirmaries have no trained nursing, the nursing being entirely in the hands of pauper women, most of whom have come in burthened with children. Be it remembered, these women have to take charge of serious medical and surgical cases as well as of the lunatic patients: in sixty-one infirmaries the latter are in charge of paupers both night and day, and, in short, in almost all of them the nursing is quite insufficient and inefficient; in sixty-five the beds and pillows are of the roughest description, being merely bags filled with straw; in six only is there satisfactory ventilation; in fifty-nine the sanitary arrangements are of the most disgusting character imaginable—in fact, there is an absence of all sanitation; in forty-three there are neither plates, knives, nor forks for the poor inmates to eat their food with. Without going further into particulars, we may say there is in almost all an absence of proper food, nursing, sanitation, and comfort for those poor creatures who are compelled by dire necessity to enter these institutions, which the public would find it difficult to believe. We would, therefore, call upon the boards of guardians and the public to examine into these matters for themselves, and give us their active sympathy and help that this uncouth system may be improved and altered—that the infirmaries may no longer be disgraceful to this country, but provided with the proper necessities, conveniences, and comforts, as in any hospital for the sick."

We are happy to give publicity to this letter and to join our voice to those of the chairman and honorary secretary of the council of the Irish Medical Association in enforcing upon the local guardians and the Irish public itself the necessity of examining first hand the conditions of their workhouses and workhouse infirmaries. It is just thirty years since we

commenced in these columns drastic criticism of the management of our workhouses and workhouse infirmaries. The series of articles we then published, which had their origin in the story of the deaths of inmates of the Holborn and St. Giles's workhouses, resulted in a great humanitarian movement in the metropolis and furnished the British public with a capital object-lesson as to the power of the press. Much remains still to be done both in London and in the provinces in workhouse reform, but the communication from the chairman and honorary secretary to the council of the Irish Medical Association shows that in Ireland even a beginning has to be made. Surely such crying abuses will not in these days be left to the remedial assistance that a few zealous philanthropists, a few outspoken journalists, and a few practical Christians may be able to give. The people of Ireland as a whole should see to the matter for themselves. If each particular community will bring the proper pressure to bear upon its guardians the latter can be made to ameliorate, at any rate, the grosser conditions with remarkable alacrity.

THE FUTURE OF CHARING-CROSS HOSPITAL.

A STARTLING proposal has recently been made with regard to Charing-cross Hospital—namely, that the institution should be transferred to Battersea or Camberwell. That this would be a great advantage to South London we can imagine, but that it would aid the hospital in its financial position is, we think, more than doubtful, unless, and we assume this to be a fact, the present site and buildings are the property of the hospital. This being the case, the authorities could doubtless, with the money thus obtained, build a new hospital and school in a district where land is less valuable, and have a balance in hand. But consider the future. Would the subscriptions from the neighbourhood be as large, would the school be as popular, and would not the work be crippled even more than now on account of financial difficulties? A correspondent, writing in the *Times*, says in its new position the hospital would serve a much larger country area. To our thinking this is just what a metropolitan hospital should not aim at doing. The needs of London afford ample scope for the energies of any hospital. Another question to be considered is the convenience of the staff. Camberwell is much farther away in point of time from the consultants' quarter than Whitechapel or Hammersmith. In the *Times* of June 5th there is a letter signed "Southerner," who says: "There are many suitable men residents in the southern districts who would be willing to devote a certain portion of their time and means." For the managing board this would be all very well, but for the visiting staff let us remember that not everyone can bend the bow of Odysseus. The skill and learning of the general practitioner have been necessarily exercised in a different direction to those of the medical officer of a hospital staff. Neither can at a moment's notice replace the other, and each body would be equally ready to acknowledge this.

SPASTIC AND TABETIC TYPES OF GENERAL PARALYSIS.

IN a recent number of the *Journal of Mental Science* there is a paper on this subject by Dr. R. S. Stewart, who points out that cases of general paralysis are more or less roughly grouped in two classes, in one of which the clinical symptoms and pathological changes indicate a more or less close relationship to tabes dorsalis, while in the other the resemblance is to the conditions found in cases of lateral sclerosis. Dr. Stewart bases his views on an examination of the conditions found in 317 cases of general paralysis treated during the last ten years in the Glamorgan County Asylum. He found that the proportions of the two types per cent. were very unequal, 85 per cent.

being of the spastic type, while only 15 per cent. were tabetic in character. He also finds that, whereas in general paralysis as a whole the average age of onset is thirty-nine, in the spastic type it is thirty-eight and in the tabetic forty-one; and he points out that, according to Dr. Gowers, lateral sclerosis as a disease is more frequent than tabes dorsalis between the ages of twenty and thirty, and less frequent between the ages of forty and fifty. Taken generally also the tabetic cases have a longer duration than the spastic, and congestive seizures are more common in the latter than in the former. Thus, these seizures occurred in 72 per cent. of the spastic cases and in only 65 per cent. of the tabetic. Many of the tabetic cases, however, in their later stages become complicated with symptoms of lateral sclerosis, and in such cases congestive seizures are by no means rare. Again, in the two types a difference is found to exist in the character of the mental change which is present, melancholia being the rule in tabetic cases and mania in those of the spastic type. A comparison of pathological conditions also shows a greater diminution in brain weight in cases of the spastic type; while in the spinal cord, in cases of the tabetic variety, the shrinkage is greater antero-posteriorly, and in the spastic cases in the lateral diameter. There are other points of distinction, Dr. Stewart adds, but these are sufficient, as indicating the more prominent ones, to show that in general paralysis there are two more or less distinct varieties—one occurring in association with lateral, and the other in association with posterior sclerosis. The relation of the brain condition to the spinal condition he does not regard as in any way secondary. Both the cerebral and the spinal changes he regards as part of a widely spread morbid process.

THE HEALTH OF MR. GLADSTONE.

WE are glad to have authority for stating that Mr. Gladstone's attack of bronchial catarrh has been of a very slight nature. He was kept to his room for two or three days as a matter of precaution. On Wednesday morning Mr. Gladstone was much better, his pulse and temperature were normal, his cough was nearly gone, and he was allowed to go into another room.

SANITARY IMPROVEMENTS AT RHYL.

ON Whit-Monday the urban district council celebrated the completion of the new sewerage scheme at Rhyll, carried out by the advice and under the supervision of Mr. Baldwin Latham. Sir Charles Cameron of Dublin was present, and invitations were sent to about forty medical officers of health of the large midland and other towns. These were extensively accepted, and Mr. Baldwin Latham conducted the party over the works and explained the scheme and the apparatus. The large storage reservoir, which is unique in construction, can contain 382,000 gallons, nearly treble the maximum amount ever likely to be collected, and discharges twice a day within about an hour of the first ebb tide by an 18-inch iron pipe carried three-quarters of a mile into the sea and bent towards its outer end so as to suit the tidal current. The engine-house contains six gas engines, two smaller engines being used for ordinary pumping, two larger being used in dealing with storm water, and the remaining two small engines being employed in working a screening apparatus. All the engines are in duplicate, and each is complete in itself and entirely independent of the others. An automatic gearing apparatus controls the action of the pumps, so that while the engine works uninterruptedly the pumping goes on only when there is material to be removed from the discharging end of the sewers. The town sewers have all been reconstructed of new materials laid down on concrete foundations. All dead-ends are fitted with

automatic flushing tanks, and the whole system is ventilated by lofty shafts so constructed as to diffuse the sewer-air into the atmosphere at once. The chief features of this system in a town where many difficulties had to be surmounted are constant discharge from the town sewers, perfect flushing and ventilation, and the absence of tide-locked sewers. The advantages of the system were abundantly evident in the total absence of smell in the pumping house and the storage reservoir. Mr. Baldwin Latham stated that the scheme had been carried out in twelve months at a cost of £30,000, and that Rhyl was the third town in the United Kingdom, in point of time, to adopt a system that was perfect in every feature.

TYPHOID FEVER AT PLUMSTEAD AND WOOLWICH.

THE somewhat severe outbreak of typhoid fever at Plumstead and Woolwich, the occurrence of which we announced last week, appears now to have terminated; at any rate, in the sanitary district of Woolwich there has not been a case for the last few days. The outbreak was decidedly severe in Plumstead; 120 cases are known to have occurred in the district, and the outbreak was supposed to have taken its origin in a certain dairy. This dairy has been closed, and samples of water and milk from it have been sent to Professor W. R. Smith, medical officer of health of Woolwich, for bacteriological investigation. No typhoid fever organisms have been found. In Woolwich 21 cases occurred, and here again the dissemination of the mischief seems to have been due to a dairy. But the owners of the Woolwich dairy would seem to point to the owners of the original incriminated dairy at Plumstead as the real source of the trouble, as they state that they have made up their supply of milk by adding to it a gallon of milk from the Plumstead dairy. There are, we understand, no cases among the cadets at the Royal Military Academy.

REAL CHARITY.

THE town of Holbeck, near Leeds, has just embarked upon a laudable enterprise. Last winter a relief committee, organised to deal with the distress arising from the prolonged frost, became aware that there were always cases needing assistance of one form or another. Therefore a social and sanitary improvement committee was founded to carry out such work as providing convalescent home letters and sending poor children into the country under the auspices of the organisation already existing for that purpose. The committee further ascertained that the consultants of the town are willing to give their services free in any case of poverty where a second opinion is needed and the patient cannot be moved to the hospital. The committee also inquire into sanitary conditions and bring defects to the notice of the authorities. Of course, there is nothing new in such a body; it is only a revival of the functions of the deacons and parabolani of the Primitive Church, but an organisation such as this makes for the unity of Christendom far more than any amount of Grindelwald picnics, and we wish it every success and the compliment of imitation.

THE EASY ACCUSATION OF THE PROFESSION.

THE chief feature of a recent inquest at Carmarthen on a little girl unfortunately drowned was a long reflection by the coroner on the evil behaviour of a medical practitioner in hesitating to rush to the case when summoned on the ground that he did not see who was going to pay him. This censure of a professional man was founded on the unsupported evidence of an ironmonger's apprentice, and apparently in the absence of the accused gentleman. Surely the least the coroner could have done would have been to

have summoned Mr. Bowen-Jones before blaming him. It was not in evidence that the fate of the unfortunate child was in any way affected by what Mr. Bowen-Jones did or did not do. The child had been in the water a quarter of an hour when she was taken out, apparently quite dead. Artificial respiration was immediately used, first by the storekeeper and then by Dr. Parry, who arrived in a quarter of an hour. We should have no apology to offer for a medical man who was summoned to a case of drowning and declined to go till the question of his fee was settled. But we protest against a coroner lightly taking such statements as evidence against a member of the medical profession and passing judgment on him in his absence, and in leading the jury to do so. It is the duty of a coroner to confine his inquiry to the ascertainment of the cause of death and to refuse to entertain aspersions on a practitioner's conduct by a boy who confessed that he did not make the medical man understand that it was a case of drowning, and contented himself after his unsuccessful visit with going home.

THE ANNUAL REPORT OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

THE annual report for 1893, prepared by Mr. Shirley F. Murphy, medical officer of health for the county of London, has just been issued. It contains elaborate statistical tables, as well as much valuable information of other kinds, and merits the extended notice which we shall give it shortly. Mr. Murphy estimates the London death-rate for 1893 at 20.9 per mille, being a slight increase on the average of the preceding decennium, but, nevertheless, being lower than that of Liverpool, Manchester, and Salford. The general zymotic death-rate of London for 1893 shows a slight increase on that of preceding years.

"RETURN" CASES OF SCARLET FEVER.

THIS subject is so often approached either exclusively from the view point of the medical officer of health or from that of the fever hospital medical superintendent that it is refreshing to be able to refer to cases where the medical officer of health acts in a dual capacity and is responsible for the disinfection both of infected houses and of discharged patients. Such cases are recorded by Dr. Cooper-Pattin, medical officer of health of Norwich, who reports that during 1894 eleven cases of scarlet fever occurred in connexion with patients discharged from the Norwich Fever Hospital. In endeavouring to explain the origin of these "return" cases, Dr. Cooper-Pattin observes that in some instances rhinorrhœa, which had ceased at the time of the patient's discharge from hospital, recurred after a short interval and was apparently instrumental in conveying infection to other members of the family. He thinks, and we believe there are many medical officers of fever hospitals who hold the same opinion, that nasal discharges set up by scarlet fever retain for a long period of time an infective quality. Secondary peeling—a manifestation to which we have on former occasions referred—took place in some of the cases under Dr. Cooper-Pattin's care, and he mentions one where a boy who had desquamated completely prior to his discharge from hospital was readmitted three weeks later with secondary desquamation manifesting itself. He is of opinion that these secondary desquamations account for the occasional occurrence of "return" cases, and he further thinks that in five of the eleven cases above referred to the source of infection was the recurrence of rhinorrhœa. Certainly there is an accumulation of evidence pointing to recurrent nasal discharges as a source of infection, but we have not ourselves come into contact with cases where the awakening of infection in a discharged patient's family suggested secondary desquamation.

as the cause of it. However, it is a difficult matter to dogmatise upon, and we must remain on the look-out for evidence. "Return" cases of scarlet fever are certainly sometimes associated with unfinished primary peeling, but whether after intervals of some three or four months the two phenomena stand in relation of cause and effect is perhaps hardly demonstrated. We notice, too, with interest that Dr. Cooper-Pattin regards three of the "return" cases alluded to as due to the exposure of infected clothes put away in the early stages of the patient's illness, before perhaps its nature was recognised. A short time since we asked, "What is 'Premature Discharge' from a Fever Hospital?" and we commend the above considerations to those who, with ourselves, are anxious to furnish an answer to the question.

AMERICAN ELECTRO-THERAPEUTICS. I.—

THERE appears to be a "boom" in electro-therapeutics on the other side of the Atlantic which is conspicuous by its absence on this. Nor is it a mere fashion of the day; there is solid work behind it. The American Electro-therapeutic Association is evidence of this. Established on the usual lines of other medical societies, this association presents one very exceptional feature. The Fellows "shall either be practitioners of medicine of good standing or electrical experts." The wisdom of such a rule may be open to question, but its aim is obvious and its intention excellent. It proclaims a due recognition of the principle that in electro-therapeutics "the physical problem underlies the biological one," and its object is to attain a higher standard of medical education in the physics of electricity. The annual report of the Society's transactions for 1894 does not seem yet to have reached this country, but in 1893 the association consisted of about eighty Fellows. Its various committees then submitted reports on standard coils, standard meters, static machines, constant current generators and controllers, electrodes, etc. The latter committee appears to be a standing one, and furnishes an example of painstaking and methodical work. Its chairman has addressed a circular which now lies before us, "to every manufacturer of electro-therapeutic apparatus whose address is known" in order to secure "the universal adoption of uniform connexions, a standard gauge of screw throughout construction, and efficient, durable, simple, and interchangeable electrodes." The report of this committee and the discussion thereon will form part of the proceedings of the society at its meeting in Toronto on Sept. 5th. Such a committee has much useful work before it. If in electro-therapeutics results are to be compared and a definite procedure followed, there is an evident necessity for the use of electrodes of a definite size and shape, easily procurable, and with distinctive designations. It is evident, for example, that a current strength (intensity) unbearable through an electrode of a certain size may be easily and painlessly passed through one of a greater surface area. It is long since the necessity for standard electrodes was recognised and advocated by Erb. Important steps in this direction were taken at the society's meeting two years ago, and it was also recommended on that occasion that all connexions be by "standard hole and pressure screws." The adoption of this simple detail would "soften the lot and sweeten the temper" of many a practitioner sorely tried by the treacherous and even dangerous insecurity of certain "plug and socket" connexions.

DR. NESTOR TIBARD has been appointed Secretary to the Pharmacopœia Committee of the General Medical Council.

THE Corporation of the City of London have made a grant of 30 guineas towards the funds of the Surgical Aid Society.

Pharmacology and Therapeutics.

PHOSPHO-GLYCERATE OF LIME.

DR. LAFAGE has recently published in the *Tribune Médicale*¹ an account of a number of cases in which he employed the phospho-glycerates of lime with advantage. These substances were brought to the notice of the profession last year by M. Robin, who communicated a paper upon their physiological and clinical properties to the Paris Académie de Médecine,² in which he showed that they increase the general nutrition of the body by means of the nervous system in certain forms of neurasthenia, where there is a want of muscular strength, incapacity for mental work, insomnia, and giddiness. Phospho-glycerate is also useful in ataxia, some paralyses, phosphaturia, chlorosis, anæmia, phthisis, and in the convalescence from acute disease, more especially in that following influenza. In these last cases Dr. Lafage has used phospho-glycerate of lime in the form of wine, syrup, and capsules and has obtained remarkable results, the impaired strength improving in the most rapid manner. He also mentions cases in which this drug appeared to have re-established the secretion of milk in nursing women where it had failed.

EXTERNAL USE OF GUAIACOL.

The *Journal de Praticiens* (March 16th, 1895) gives an account of the successful external use of this drug by M. Brice. It was given in 4 cases of pneumonia, 5 of typhoid fever, 4 of phthisis, 1 of bronchitis, and 1 of rheumatism. The amount applied each time was 1 to 2 cubic centimetres. Larger doses produced profuse sweats, with tendency to collapse.

TREATMENT OF WHOOPING-COUGH BY MANDELATE OF ANTIPYRIN.

The same number quotes M. Rehn's experience of this preparation, which appears to have been successful and not followed by any of the poisonous symptoms which have occasionally been known to follow the use of antipyrin in this disease. The salt is obtained by treating antipyrin with mandelic acid and M. Rehn prescribed it in sixty cases in children of various ages. In all the cases except two the paroxysms rapidly diminished in number, the appetite improved, and vomiting ceased, and M. Rehn attributed this to the sedative action of the drug. The dose given was five to ten centigrammes for children of three to five years of age.

DERMATOL IN OPHTHALMIC PRACTICE.

Dermatol, which is a subgallate of bismuth and has been employed in eczema and various skin diseases, is said by Dr. Romeo Roselli to be very efficacious in many forms of inflammation of the eye, causing effusions to be absorbed and possessing an astringent, drying, and cicatrising action. In bactericidal power it is more active than insoluble powders, such as calomel or iodoform, and rapidly disappears itself, probably by being absorbed. It is very useful in simple keratitis without photophobia or marked conjunctival hyperæmia, in corneal ulcers (especially in those of a traumatic origin), and even in diphtheritic conjunctivitis, but it is of very little good in blepharitis or in granular lids. The only objection to its use is that it causes smarting and lachrymation for a few minutes. Dr. Roselli's observations were made both on patients in the Eye Clinic and on animals in which inflammation had been produced by the *staphylococcus pyogenes*.

LACTIC ACID IN CORNEAL ULCERS.

Lactic acid, which is said by M. Mosetig to exhibit a partiality for diseased tissue, destroying it while leaving untouched healthy parts, has been found by Dr. Delschenoff very useful as a local application in corneal ulcers. In chronic cases with intense photophobia and marked hyperæmia of the vessels surrounding the cornea a single application of a 50 per cent. solution of lactic acid made with a pointed bit of wood generally enables the patient to bear the light quite well, and sometimes is sufficient to prevent the ulcer spreading, especially if it has not already attained any very considerable dimensions. An eschar is of course formed, which falls off in three or four days, revealing a healthy base, which is seen to be already commencing to cicatrise. The application of the acid is not painful, and if by accident a healthy

¹ Quoted in *Le Scalpel*, March 31st, 1895.

² *THE LANCET*, Nov. 10th, 1894.

part of the conjunctiva is touched the effect is so slight that by the next day the epithelium will be found to be replaced.

ANTIPIRYN AS A HÆMOSTATIC.

The hæmostatic effect of antipyrin has been noticed by MM. Huchard, Henocque, and Olikoff,³ though some other observers have not been able to confirm their statements. A remarkable instance of its power of rapidly coagulating blood in a very critical case has recently been published by Dr. Broussolle,⁴ surgeon to the Dijon Hospital. The patient had a large aneurysm affecting the transverse portion of the aorta which had encroached upon the walls of the chest so as greatly to thin the integuments. A rupture took place, and at first firm pressure on the sternum was used, which temporarily diminished the copious flow of blood, but the hæmorrhage was as violent as ever the moment the pressure was relaxed. Under these circumstances Dr. Broussolle determined to try the effect of antipyrin. After rapidly clearing away the clots from the skin a drachm of antipyrin was sprinkled on the wound and a pad of absorbent cotton wool applied with a bandage. The effect of the antipyrin was first to form a clot, which caused the hæmorrhage to diminish and ultimately to stop. It did not return, though the patient lived for forty-eight hours and died from pulmonary complications of long standing. The pad was found to be scarcely stained, and the size of the aneurysmal tumour had decreased to a marked extent.

THERAPEUTICS OF HEPATIC AND RENAL COLIC.

Mr. Fleiner has for two years investigated the mode of treatment which consists of injections of oil in cases of hepatic colic, and on the whole thinks it preferable to the administration of oil by the mouth, as much larger doses can be tolerated and more frequent repetition is well borne. The oil is supposed to act as a purgative and cholagogue, and so to favour the expulsion of calculi which have become arrested in the biliary ducts. This treatment may be continued over a long period of time and does not lose its purgative effect. From 300 to 500 grammes of pure olive oil should be given, and to attain success the injection should be made very slowly. It should be repeated every day for the first seven days, and then gradually reduced at first to every two days and then every three days, and so gradually dispensed with. The following prescription is also recommended for both hepatic and renal colic: Valerianate of amyl, sulphuric ether, of each three minims; to be made into capsules; two capsules to be taken every half-hour until six have been taken in the day. Amyl valerianate has a sedative and stimulating action, and in hepatic colic is said to be a specific, not only suppressing the attack, but dissolving cholesterin and preventing its return. In renal colic it is not so radical in its action, but eases the pain of the attack.

THE APPROACHING REVISION OF THE BRITISH PHARMACOPOEIA: NEW ORGANIC REMEDIES.

Messrs. Helbing and Passmore have just published in brochure form some good and useful suggestions, embodying what they consider should be the Pharmacopœial requirements of the new organic remedies. Their conclusions are evidently based upon a practical and intimate acquaintance with the drugs described. As representing the later remedies which synthetic chemistry has recently placed at our disposal, and the use of which has been justified by extended clinical observation, the following are mentioned:—chloralamid, dermatol, formaldehyde, guaiacol (crystalline), ichthyol, naphthalene, naphthol, phenocoll hydrochloride, piperazine, resorcin, salol, and trional. No exception can be taken we think to the suggestions in regard to the necessity for more stringent requirements for lanoline, saccharin, and sulphonal, and also in regard to some minor alterations in the characters and tests of acetanilide, antipyrin, paraldehyde, and phenacetin. The paragraphs dealing with the suggested pharmaceutical text for each remedy, and containing the character and tests by which purity and uniformity are to be recognised, are distinctly good and such as convey the impression that they could only have been the outcome of actual laboratory observation.

³ THE LANCET, Oct. 29th, 1887, p. 880.

⁴ La Semaine Médicale, April 10th, 1895.

THE MEASUREMENTS OF THE SKULL OF SIR THOMAS BROWNE.

By CHARLES WILLIAMS, F.R.C.S. EDIN.

SIR THOMAS BROWNE died on Oct. 19th, 1682, and was buried in the church of St. Peter Mancroft, Norwich. In 1840 his skull was "knaved out of its grave" by the sexton. It appears that some workmen who were employed in making a grave for the incumbent's wife accidentally broke into the vault which contained the coffin of Sir Thomas Browne. In some unexplained way they fractured the lid of the coffin, and thereby exposed the skeleton. The sexton did not consider it an act of sacrilege to take possession of the skull and to offer it for sale. Eventually the late Dr. Edward Lubbock became its possessor, and in 1845 the skull was deposited by him in the pathological museum of the Norfolk and Norwich Hospital, where it is still to be seen. It has recently been claimed by the vicar of St. Peter Mancroft, but unsuccessfully. The hospital authorities refused to relinquish the precious relic, and there it remains under its glass case, reverently preserved and protected, and long may it remain, not as an object of curiosity, but as a means of directing the attention of visitors to the learned works of that great scholar. The coffin plate of brass was also broken lengthwise at the same time. On it were engraved the remarkable lines, most probably written by his eldest son, Edward: "The best bred man" of Charles II.'s Court, President of the College of Physicians, and Physician to St. Bartholomew's Hospital. "*Hoc loculo indormiens corporis spagyrici pulvere plumbum in aurum convertit.*" It is a singular circumstance that the lead of which the coffin was made was found to be completely decomposed and to have changed to a carbonate which crumbled at the touch.

The measurements of the skull are expressed in English inches and tenths, and have recently been taken by means of Flower's craniometer, according to the plan suggested and carried out so extensively by the late Dr. Barnard Davis, the possessor of 1800 human skulls, recently deposited in the Museum of the Royal College of Surgeons of England, and to whom, as well as to Dr. Thurnham, the science of anthropology is so deeply indebted for the production of that great work, "Crania Britannica." The skull may be placed in the dolicho-cephalic class. It is quite edentulous, but is in a state of excellent preservation. The forehead is remarkably low and depressed; the head is unusually long, the back part exhibiting a singular appearance of depth and capaciousness. The following are the measurements:—Internal capacity, in ounces avoirdupois of dry sand, 69 ounces. Circumference round the forehead about an inch above the naso-frontal suture and over the most prominent part of the occiput, 21.5 in. Fronto-occipital arch, from the fronto-nasal suture along the centre of the calvarium to the posterior edge of the foramen magnum, 15 in.—(a) length of the frontal portion, 5 in.; (b) length of the parietal portion, 5 in.; (c) length of the occipital portion, 5 in. Intermastoid arch, from the tip of one mastoid process across the vertex to the tip of the other, 14.5 in. Longitudinal diameter, or length from the glabella to the most prominent point of the occiput, the glabella being regarded as about an inch above the naso-frontal suture, 7.7 in. Transverse diameter, or greatest breadth—interparietal, 5.8 in.; intertemporal, 5.4 in.—(a) frontal breadth at the most divergent points of the bone in the coronal suture, 5 in.; (b) parietal breadth at the protuberances, 5.6 in.; (c) occipital breadth at the junction of the occipital with the posterior inferior angles of the parietals, 4.8 in. Height from the plane of the foramen magnum at its centre to that of the vertex, 5.1 in.; (a) frontal height, 5.5 in.; (b) parietal height, 5 in.; (c) occipital height, 4.8 in.; taken from the axis of the auditory foramina these measurements are respectively 4.3 in., 4 in., and 4.5 in. From one auditory foramen to the other—(a) over the most prominent part of the frontal bone, 11 in.; (b) over the parietal bones, 12 in.; (c) over the occipital bone, 13 in. Length of the face from the nasal suture to the tip of the chin, an allowance of 0.6 in. being made for the absent teeth and absorption of alveolar ridges, 4.5 in. Breadth of the face from the most prominent point of one zygomatic arch to that of the other, 5.2 in.; from the external border of one orbital ridge to that of the

The Dean of Rochester presided last week at the Church House at the annual meeting of the Church Sanitary Association. The proceedings closed with a paper upon "Public Slaughter-houses and the Proper Inspection of Meat," by Dr. J. F. J. Sykes, medical officer of health for St. Pancras.

other, 4·2 in. Width of the lower jaw at the angles, 4 in. Proportion of the greatest breadth to the length (the latter taken as 100), 0·72. Proportion of the height to the length, 0·66. The above measurements were taken at the request of the late Dr. W. A. Greenhill of Hastings, who, at the time of his death in October, 1894, was engaged in preparing for the press a new edition of Sir Thomas Browne's "Urn Burial." It was his wish "to make the account more complete by giving the measurements of that great man's skull." Is it not strange that one who meditated so deeply on the transitory duration of monuments and the great mutations of the world should have exemplified in his own relic his words to Thomas Le Gros? "But who knows the fate of his bones, or how often he is to be buried? Who hath the oracle of his ashes, or whether they are to be scattered?"

Norwich.

ROYAL MEDICAL BENEVOLENT COLLEGE.

DR. HOLMAN presided at the annual general meeting of this institution on May 30th, when the report for the past year was presented to the governors and unanimously adopted. The report, which is a very satisfactory document, states that the full number of pensioners and foundation scholars has been maintained, and that there has been a slight increase in the receipts from annual subscriptions, upon which income the benevolent side of the institution in a great measure depends. The continued success of the school has compelled the council to give serious attention to the question of extending the accommodation, and it has been decided to build a lower or junior school capable of accommodating 100 boys. As many of the boys come to the college with a very limited education, this will be of immense benefit to them. The seating accommodation of the chapel has been inadequate for some time past, and with an addition of 100 boys its extension will become absolutely necessary. Plans for this purpose have been submitted by Sir Arthur Blomfield, and contributions to the amount of about £1175 are already in hand, but further subscriptions are urgently needed. In a few months the college will possess its own laundry. This is desirable, both from an economical point of view and also as a safeguard from the risk of infection. In accordance with the Act of Parliament which came into force on July 1st, 1894, the college is now open to all classes of boys, although special privileges are reserved for the sons of medical men. The gift by Mr. France of a ninth perpetual presentation to the School of St. Anne's Society for the orphan daughters of medical men has been completed; and the council are happy to report that under the provisions of the will of the late Mr. Bowen of Melbourne a considerable residuary estate is left to the college to be employed in the amelioration of the condition, or otherwise for the benefit, of the widows and orphans of medical men from time to time under the care and protection of the college. The council propose to increase the out-pensions from £21 to £30 per annum on and after July 1st, 1895. As it is upon the income from annual subscribers that the success of the charitable side of the college mainly depends, the council earnestly ask everyone interested in the institution to endeavour to obtain more annual subscribers. The progress of the school is well maintained. Several scholarships have been gained, and almost every Epsomian at Cambridge who is a scholar of his college had his scholarship either increased or extended, which speaks well for the training they received in the school in the past. The health of the boys has been remarkably good; work and discipline have been satisfactory; and the continued interest taken by the boys in their games is a healthy sign. Both cricket and football have been played with vigour.

It is probable that before July next there will be some vacancies for exhibitors, who must be sons of some of the less fortunate members of the medical profession. Application should at once be made to the secretary at the offices in St. O-square.

Dr. HOLMAN, in proposing the adoption of the report, remarked that the school was full to overflowing, and it had been decided to build a lower school, to enlarge the chapel, and to erect a laundry. As they were now in the flood-tide of success, it would be impossible to stand still, and they

must go forward. Referring to the generous gift from the late Mr. Bowen of Melbourne, the Chairman said the council had met with very inefficient support from their brethren in England, and they had been pushing the claims of the college in all parts of the world. A South African paper had published a leading article on the merits of the college, and only about a week ago a subscription had been received from Hong-Kong. Dr. Harvey of Calcutta had moved very actively in the matter in India, and two subscribers of £10 a year had been added to the list. Adverting to the new Act of Parliament which had been passed for the benefit of the school, he said that when the asylum was empty it would be used for school purposes, but the school would pay a rental which would go towards the benevolent part of the work. Under the Act they had powers to borrow, and for the proposed extensions it would be necessary that these powers should be used.

The retiring members of the council, Dr. M. Baines, Dr. R. H. Bradley, Dr. Charles Drage, Colonel Gordon Watson, Mr. J. J. Purnell, Mr. H. E. Vardon, Sir Edward Sleveking, Sir Arthur Watson, Mr. C. L. Smiles, and Surgeon-Major De Tatham, were re-elected for a further period of three years, and the proposed increase to the out-pensions in consequence of the legacy of Mr. Bowen of Melbourne was agreed to.

The new by-laws received the approval of the Governors, the auditors were reappointed, and a vote of thanks to the Chairman for his great services as treasurer and for his able conduct in the chair brought the meeting to a close.

The lists of successful candidates for the pensionerships and for the foundation scholarships were published in THE LANCET of June 1st. There is no vacancy for a Fugh pensionership or for a Morgan annuitant.

THE ELECTION TO THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, AND THE HALF-YEARLY MEETING OF THE FELLOWS OF THE COLLEGE.

NOTICE has been given that "a meeting of the Fellows of the Royal College of Surgeons of England will be held at the College in Lincoln's-inn-fields, on Thursday, the 4th day of July next, at 1.30 o'clock in the afternoon precisely, for the election of five Fellows into the Council of the College." Intending candidates may be reminded that "blank forms of the requisite notice from a candidate and of his nomination may be obtained on application to the secretary, and that the same must be received by him, duly filled up, not later than on Monday, the 10th of June next." Candidates are as liable as other people to make mistakes, either of commission or omission, and delays in providing themselves with the necessary forms, in getting them properly filled, and in transmitting them to the secretary in time may prove dangerous or fatal to their prospects of election. Last year a casualty occurred, and on another occasion the friends of an intending candidate were kept employed all day in rectifying his inadvertent omissions to comply with the official requirements, with the result that it was only upon the stroke of twelve at midnight on the last day for the reception of applications from candidates that his papers were lodged inside the doors of the College.

It is satisfactory to note that the election will be held under an amended by-law (Section IV.), and that Fellows of the College will no longer be required to apply for voting-papers. A voting-paper will be sent by post to each Fellow whose address in the United Kingdom is registered at the College on Saturday, June 22nd next.

Notice has also been given to the Fellows that a meeting of the Fellows will be held at the College on Thursday, July 4th next, at 5 o'clock P.M., for the following purposes:

1. To read the minutes of the half-yearly meeting of Fellows on Jan. 3rd last.
2. The President to report proceedings in connexion with the application to the Secretary of State for alterations in Sections IV., XVI., and XXV. of the By-laws.
3. To read the following resolutions adopted by the Council on Feb. 7th, 1895, in reference to the resolution

adopted at the last meeting of Fellows requesting the Council to appoint a conjoint committee of members of the Council and other Fellows of the College to consider the desirability of obtaining a new Charter—viz.: (a) that in accordance with the opinion of the legal advisers of the College, the Council do not deem it expedient to accede to the resolution passed at the meeting of Fellows held on the 3rd ultimo; (b) that a committee of the Council be appointed to receive deputations from the Fellows of the College upon the subject of the resolution of the meeting of Fellows of Jan. 3rd last and to report thereon to the Council; (c) that copies of the two foregoing resolutions be forwarded to the mover and seconder of the resolution of the meeting of Fellows.

4. For the consideration of any motions which may be introduced by Fellows, in accordance with Clause 6, Section XXIII. of the regulations of the Council, relating to meetings of Fellows.

It is added that motions must be signed by the mover or by the mover and other Fellows, and must be received by the secretary not later than Wednesday, June 12th next.

RECENT IMPROVEMENTS IN THE PRODUCTION OF COD-LIVER OIL AND CASTOR OIL.

CHIEFLY through the interesting and important researches of Heyerdahl it is now known that cod-liver oil can be prepared not only free from objectionable taste but also from the tendency it has after administration to cause unpleasant eructations. The first improvement—viz., that of taste—was effected on the introduction of what is known as Peter Müller's steam process, which, when properly carried out, produces an oil absolutely free from decomposed albumens and consequently from repulsive taste, but still not from the tendency to set up irritation in the stomach, with eructation as a sequel. The latter very disagreeable property was ultimately removed when the cause was made known by the investigator just mentioned. Thus Heyerdahl showed that the fats of cod-liver oil (which he named *therapin*, 20 per cent., and *jecolein*, 20 or more per cent.) are entirely different from other fats, and that one of their most remarkable characteristics is a much stronger tendency to form hydroxylated compounds than that possessed by all other known fatty substances. The formation of hydroxy-acids is probably the true cause of the rancidity, and therefore of the irritating and repeating qualities of the oil, while as the medicinal value of the oil depends on these fatty acids, combined of course in the form of glycerides, it is obviously desirable that these glycerides should be retained in the oil absolutely unimpaired. This end is accomplished by completely excluding the fats from the action of free oxygen throughout the whole process of preparation. This is effected by keeping the oil under an atmosphere of carbonic acid gas from the moment it leaves the liver cells till it is bottled and corked. Samples of cod-liver oil said to be prepared in the manner described have been recently submitted to us for examination by Messrs. Müller and Co., 43, Snowhill, E.C. In view of the care and skill which are exercised during the course of its preparation, it is hardly surprising to find that the oil is what it is stated to be—free from objectionable taste and smell, of a pale straw colour and according to our examination of a specific gravity at 60° F. of 0.9275. The specimens afforded, indeed, distinct evidence of the success which has deservedly attended the long and painstaking research instituted by Messrs. Müller, the results of which are not only satisfactory in having manifestly cleared up some obscure points in regard to the composition and constitution of cod-liver oil, but also in that it has led to a means of preparing one of the most powerful nutrients at the physician's disposal, and that in a form which is most acceptable for administration.

Curiously enough, we have had brought before our notice almost simultaneously with the foregoing an improved process for the production of castor oil, in which precautions similar in kind to the process described in the preceding paragraph are adopted. Indeed, it is not unlikely that under the oxidising influences of the air castor oil is susceptible to the same changes as cod-liver oil. There is no more valuable

and useful member of the *materia medica* than castor oil, and as a safe and efficient cathartic it stands alone; but as everyone knows it is commonly repulsive to the taste, and, unfortunately, this drawback proves frequently strong enough to render its administration impossible, except perhaps in capsules or when it is highly flavoured and the original taste masked by a strong and agreeable aromatic. It has recently been made perfectly clear to us, however, that the repulsive taste of castor oil can be largely if not entirely obviated by a better mode of extraction of the oil from the seed, and by adopting certain measures in carrying out refinement prior to bottling. It appears that the opinion has hitherto been that the seed must first be ground so as to break the oil cells before they are submitted to the crushing process, whereas it has been shown by Mr. Mitchell, of the British Castor Oil Company, 47, Victoria-street, Westminster, that this treatment previously to the application of direct pressure is unnecessary, if, indeed, not prejudicial to the condition of the oil. All that is done in the Mitchell process, every detail of which we have inspected at the factory, is merely to press the seeds by hydraulic means (taking care so to adjust the pressure that the oil is not too forcibly expelled) first in the cold—the oil so obtained being reserved exclusively for medicinal purposes—and then raising the temperature so as to express the residual oil, which is one of the best known for lubricating purposes. After leaving the press the cold-drawn oil is forced up in vacuo into filter presses containing filter cloth of varying degrees of thickness, and after a series of refinements in this way, all conducted rigidly in vacuo and without any appreciable rise of temperature, the oil is received into bottles, from which also the air has been previously exhausted. The oil so obtained is of a clear, pale straw colour, of a specific gravity of 0.964, and remarkably free from obnoxious taste. Indeed, it will be found to possess, on the contrary, an agreeable nutty flavour, which, as has been said by Professor Atfield, "is as attractive as that of ordinary castor oil is repulsive." Unless care is taken, however, to exclude the air as far as possible from this pure cold-drawn product—if, for example, there is any neglect to keep the bottle containing it well corked—it deteriorates in course of time, as might be expected, and eventually yields a white crystalline deposit, the taste then becoming as objectionable as that of the ordinary kinds of oil. It is worth mentioning also that this oil appears to possess just twice the therapeutic effect of castor oil obtained by ordinary methods, so that it is probable that when castor oil is exposed to the air and deposits part of its fatty constituents there carry with them an important part of the valuable medicinal property of the oil. This observation suggests a line of investigation which would probably throw light on the question as to what the active purging principles of castor oil really are. Mitchell's process of extracting and refining castor oil is obviously an improvement which the profession cannot fail to approve and welcome, since in removing the great objection to the oil—namely, that of repulsive taste—as well as in securing its full therapeutic effect it is calculated to assist and to facilitate the administration of a very valuable therapeutic agent.

DIPHTHERIA IN LONDON IN 1894.

THE issue of the annual summary of the Registrar-General for 1894 enables us to ascertain how the several sanitary areas of the county of London stood during the year as regards diphtheria in its fatal form. And the result is to disclose widely differing rates of mortality from the disease in the forty-three sanitary districts into which the county is now divided. As a whole, London suffered less from diphtheria in 1894 than in the preceding year, the rate being considerably lower, and the total deaths 2670, or, with croup added, 2836, a number 646 below that of 1893, but 786 in excess of the average of the preceding decennial period. The diphtheria death-rate per 10,000 living was last year 6.1, as compared with only 3.6 as the annual average of the nine years 1885-93. If we look to the distribution of the deaths over the county, we find that of the forty-three areas there were ten which had deaths identical in number, or practically so, in both 1893 and 1894; that seven other areas had excess of

actual deaths in 1894 as compared with the preceding year; and that as many as 26 had fewer deaths last year than in 1893. In respect of locality of deaths occurring last year, it will be seen from the accompanying diagram how the several areas figure in relation to London as a whole, and in regard to the means of the five groups into which the Registrar-General divides the metropolis. One noticeable feature is that in the eastern group the several districts, with one trivial exception, all exceed the mean for London, whilst not one of the central group reaches it; and another that the mean is reached only by two districts in the western group, and would, judged by the mean of the group, be much below the line for London had it not been for the two excessive rates of Paddington and Fulham. There is but little doubt remaining after study of the diagram that the conditions of life in East London are conducive to heavy diphtheria mortality, and that next thereto those obtaining on the south side of the Thames exercise a baneful influence on the death-rate from the disease, the mean of the group being above that of London, and in itself exceeded by eight of the fifteen areas. Looking to the populous districts in the northern group, they compare very favourably with other parts of the metropolis, and outside Islington and Hackney are well below the mean.

The admissions of patients suffering from diphtheria

to hospital are given by the Registrar-General for the years 1885-94, together with the annual deaths among such cases; and we have taken out the percentages of fatality for the past seven years in this metropolitan hospital practice, the record running thus:—

Year.	Admissions.	Deaths.	Mortality per cent. of admissions.
1888	111	50	45.0
1889	740	278	37.6
1890	965	317	32.8
1891	1330	399	30.0
1892	2021	584	28.9
1893	2853	866	30.4
1894	3691	1041	28.2

The data show that, although the admissions have much increased in the period, the rate of mortality has been fairly steady in the last five years, and that with a number far in excess of any previously recorded annual statement the death-rate in hospital-treated diphtheria cases last year in London was the lowest in the list.

FATAL DIPHTHERIA IN LONDON, 1894.

In Rates per 10,000 living in each Sanitary Area, relatively to the Mean Rate for the County and for the several Groups of Districts.

(The dotted lines are the Group Mean Rates.)

RAILWAY ACCIDENTS IN 1894.

THE Blue-book recently issued giving the returns of accidents and casualties as reported to the Board of Trade by the several railway companies in the United Kingdom during the year ending Dec. 31st, 1894, sets forth some interesting and instructive figures respecting the working of our great railway systems, which go to show that many accidents might be prevented if more rigorous measures were adopted both with respect to railway servants and the general public. The number of accidents to railway servants while engaged in shunting operations might be considerably lessened if stringent rules were made and applied prohibiting jumping on and off engines while in motion; and many of the buffer accidents might be prevented if the men were severely discouraged from their foolhardy and venturesome proceedings. With passengers, too, a little thought and care would prevent many of the accidents that overtake them on the railway, but over these the companies have little control. With the railway servants it is different, and the companies should devise some means of preventing their servants from running into danger.

During the twelve months under consideration the total number of personal accidents amounted to 1185 killed and 9165 injured, but these figures include accidents which occurred upon the premises of the railway companies and in which the movement of vehicles used exclusively upon railways was not concerned. The total number of persons killed

during the course of public traffic in 1894 was 1115, and of injured 4120. Taken as a whole the figures do not show any striking comparison with those for 1893, which were 1011 and 4109 respectively; but the detailed tables bring out some interesting points. The number of persons killed and injured while passing over railways at level crossings during 1894 was 80 and 31 respectively, as compared with 55 deaths and 30 injuries in 1893. The number of trespassers killed, including suicides, was 395, and injured 137, an increase of 35 and 2 respectively. Sixteen passengers were killed and 347 injured from accidents to trains, rolling stock, permanent way, &c.; and of the companies' servants 6 were killed and 62 injured from the same causes. Of the 620 persons killed and 1052 injured by other causes than accidents to trains, including accidents at level crossings, 101 of the killed and 821 of the injured were passengers. Of these, 27 were killed and 49 injured by falling between carriages and platforms, either in getting into or alighting from carriages; 22 were killed and 16 injured while passing over the line at stations; and 16 were killed and 61 injured by falling out of carriages during the travelling of trains.

The accidents to servants of the various companies include 473 fatalities and 2649 injuries. Of these, 23 of the deaths and 298 of the injuries were caused whilst the men were coupling or uncoupling vehicles; 1 fatal case and 19 injuries are reported as being caused by the shunters coming in contact, whilst riding on vehicles during shunting, with other vehicles standing on adjacent lines; 19 injuries were caused

by standing on buffers, and 18 deaths and 196 injuries from getting on and off engines and waggons which were being shunted from one line to another.

Three passengers were killed and 159 injured while ascending or descending steps at stations, and 38 were injured by being struck by barrows, falling over packages, &c. on station platforms.

The following cases, which fortunately involved no personal injury, are instructive, inasmuch as they direct attention to possible sources of accident which increased care would prevent: 1 case of a train coming in contact with projections from another train travelling on parallel lines; 38 cases of trains running through gates at level crossings; 1 case of the bursting of boilers, tubes, &c. of engines; 387 failures of tyres; 2 failures of ropes used in working inclines; 5 failures of tunnels; 254 failures of rails; 1 case of fire in trains; and 4 fires at stations.

The evidence and reports of twenty-two inquiries into accidents instituted by the Board of Trade are included in the Blue-book, and complaint is made in several cases by the inspecting officers as to the long hours of the railway men.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Liverpool Port Sanitary District.—There were 3306 vessels inspected in the waters of this district during 1894, and of this number 2700 were British and 258 Norwegian. Notices were served in 170 cases, and only in one case was it necessary to obtain a magistrate's order. Regulations under Section 125 of the Public Health Act, 1875, for the removal of infected persons from on board ship were made by the port sanitary authority during the year. There was, Dr. E. W. Hope reports, a great reduction in the number of emigrants passing through the port during 1894 as compared with the previous year, the respective numbers being 106,147 and 167,468. The reduction was due in large part to the restrictions placed upon emigrants in the United States. Of the total number of emigrants in 1894, 53,164 were English, 2378 Scotch, and 6926 Irish. A considerable number of emigrants are rejected after medical inspection on board ship owing to unfitness of one kind or another. Varicella appears to be one of the most frequent causes of rejection, while alcoholism also ranks high.

Stoke-upon-Trent Urban Sanitary District.—The infantile mortality in this district for 1894 was 242.1 per 1000 births, the general death-rate being but 15.7 per 1000. Dr. Samuel Johnson states that the condition of the potters has been much improved during the year under review. Overalls have been adopted for all workers in dust and glaze, and mess-rooms have been provided for the employes in the lead departments. Lavatories have also been provided for the lead workers, and they are compelled to wash before partaking of meals. Respirators have been advised for all potters, but their use is at present optional.

Maidstone Urban Sanitary District.—An interesting instance of local pollution in a water-main is recorded by Mr. M. A. Adams in his current annual report. A polluted sample of water attracted attention, and it was found by some control analyses which were made that the pollution was confined solely to the water drawn from a certain hydrant. On laying bare the main it was found to be perforated at two points just below a surface gully. In-suction of polluted matter had apparently taken place, and the analysis of water drawn from the neighbouring hydrant led to its detection. Mr. Adams reproduces in the report before us the paper he read at the International Congress at Budapest on the Movements of Subsoil Water in relation to the Occurrence of Diphtheria in Maidstone. Those who attended the Seventh International Congress of Hygiene and Demography in London in 1891 will remember that Mr. Adams then contributed an interesting paper on the above subject, in which he endeavoured to show that diphtheria (1) is primarily due to the special micro-organism bred and born on the soil; (2) that, given the special organism implanted upon the soil, the initial factor that determines its propagation is the condition of the soil with respect to moisture, temperature, aëration, and organic pollution; and

(3) that its dispersal from the soil to persons living upon the soil is due to movements of the subsoil air. As a result of his further investigations, which seem strongly to support his primary conclusions, Mr. Adams would add to the above propositions: (4) that the quality of the disease, as measured by its fatal effect, is controlled by the range of the movements of the subsoil water. In the report before us there is furnished a chart showing for the years 1885-93 inclusive the diphtheria incidence in Maidstone in relation to the height and fluctuations of subsoil water. The paper is well worth reading, and a comparison between the results at Maidstone and those at other and larger districts would be instructive.

Lowestoft Urban Sanitary Authority.—It is certainly, as Mr. Francis Clarke observes, somewhat surprising to hear that in a town like Lowestoft there should be still nearly 1000 houses obtaining their drinking-water from wells many of which are shallow and receive soakage from neighbouring privies and middens. Out of twenty-six samples of well water sent to the public analyst during 1894 not one was a potable water. In connexion with the general town supply, Mr. Clarke reports that the analyses show that during the latter part of the year the filtering tanks were severely taxed by the heavy rains which then occurred. At the Lowestoft Sanatorium two of the staff contracted disease from the patients, and these cases, Mr. Clarke points out, illustrate the risk which the staff at a fever hospital incur and show the justice of basing the salaries on a liberal scale. In endorsing this statement we would add that a high degree of risk is not by any means the only drawback attached to the staff of a fever hospital.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6369 births and 3491 deaths were registered during the week ending June 1st. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 17.7 to 17.4 per 1000, further fell last week to 17.2. The lowest rates in these towns were 9.9 in Derby, 11.4 in Cardiff, 12.3 in Hull, 13.4 in Bradford, and 13.6 in Croydon; the highest rates were 21.8 in Preston, 23.0 in Burnley, 23.8 in Manchester, 27.6 in Liverpool, and 28.0 in Wolverhampton. The 3491 deaths included 347 which were referred to the principal zymotic diseases, against 304 and 354 in the two preceding weeks; of these, 91 resulted from measles, 82 from whooping-cough, 69 from diphtheria, 41 from diarrhoea, 34 from "fever" (principally enteric), 30 from scarlet fever, and not one from small-pox. No fatal case of any of these diseases occurred last week in Swansea, Huddersfield, or Halifax; in the other towns they caused the lowest death-rates in Cardiff and Croydon, and the highest rates in Gateshead, Manchester, Bolton, Plymouth, and Wolverhampton. The greatest mortality from measles occurred in Plymouth, Bolton, Manchester, and Newcastle-upon-Tyne; from scarlet fever in Burnley; from whooping-cough in Wolverhampton, Norwich, Blackburn, and Gateshead; and from "fever" in Derby. The 69 deaths from diphtheria included 41 in London, 5 in Wolverhampton, 4 in West Ham, and 3 in Leeds. No fatal case of small-pox was registered last week either in London or in any of the thirty-two large provincial towns. There were 20 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, June 1st, against 33, 27, and 29 at the end of the three preceding weeks; 1 new case was admitted during the week, against 6, 4, and 7 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1524, against 1438, 1446, and 1503 on the three preceding Saturdays; 187 new cases were admitted during the week, against 179, 185, and 214 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 240 and 245 in the two preceding weeks, declined to 194 last week, and were 90 below the corrected average. The causes of 47, or 1.4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Leicester,

Leeds, Newcastle-upon-Tyne, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Halifax, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21.1 and 20.2 per 1000 in the two preceding weeks, rose again to 21.4 during the week ending June 1st, and was 4.2 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14.9 in Leith and 16.7 in Aberdeen to 22.2 in Edinburgh and 26.0 in Dundee. The 617 deaths in these towns included 17 which were referred to whooping-cough, 17 to diarrhoea, 12 to measles, 8 to diphtheria, 6 to "fever," and not one either to small-pox or scarlet fever. In all, 60 deaths resulted from these principal zymotic diseases, against 66 and 64 in the two preceding weeks. These 60 deaths were equal to an annual rate of 2.1 per 1000, which was 0.4 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 14 and 17 in the two preceding weeks, were again 17 last week, of which 16 occurred in Glasgow. The deaths referred to measles, which had declined from 30 to 18 in the three preceding weeks, further fell to 12 last week, and included 5 in Edinburgh, 2 in Glasgow, and 2 in Leith. The fatal cases of diphtheria, which had been 4 and 3 in the two preceding weeks, rose to 8 last week, of which 5 occurred in Glasgow and 2 in Edinburgh. The 6 deaths referred to different forms of "fever" exceeded the number recorded in any recent week, and included 3 in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 109 and 103 in the two preceding weeks, rose again to 118 last week, and exceeded by 23 the number in the corresponding week of last year. The causes of 43, or nearly 7 per cent., of the deaths in these eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the five preceding weeks from 27.0 to 28.5 per 1000, declined again to 26.7 during the week ending June 1st. During the past nine weeks of the current quarter the death-rate in the city has averaged 29.6 per 1000, the rate during the same period being 17.4 in London and 19.2 in Edinburgh. The 179 deaths registered in Dublin during the week under notice showed a decline of 12 from the number in the preceding week, and included 9 which were referred to the principal zymotic diseases, against 5 and 7 in the two preceding weeks; of these, 3 resulted from diarrhoea, 2 from small-pox, 1 from scarlet fever, 1 from diphtheria, 1 from whooping-cough, and 1 from "fever." These 9 deaths were equal to an annual rate of 1.3 per 1000, the zymotic death-rate during the same period being 1.9 both in London and in Edinburgh. The 3 fatal cases of diarrhoea exceeded the number in any recent week. The 2 deaths from small-pox corresponded with the number recorded in the preceding week; since the beginning of April 14 fatal cases of this disease have been registered within the city. The death referred to diphtheria was the first recorded during the past four weeks. The 179 deaths registered in Dublin last week included 26 of infants under one year of age and 44 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the number recorded in the preceding week. Nine inquest cases and 7 deaths from violence were registered; and 64, or more than a third, of the deaths occurred in public institutions. The causes of 17, or nearly 10 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR WILLIAM JAMES BAKER, from half-pay, to be Surgeon-Major, vice G. Laffan, M.D., deceased.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain J. M. Cadell, Officiating Civil Surgeon, is appointed to the Civil Medical Charge of the Etawah District. **Surgeon-Major A. E. J. Croly, A.M.S.**, is appointed to act temporarily as Civil Surgeon at Satara, in addition to

his own military duties. The services of Surgeon-Lieutenant **W. Young**, North Lushal Hills, are placed at the disposal of the Government of the Home Department. The following officers are transferred:—**Surgeon-Major T. H. Sweeney**, from Fyzabad to Benares, as Officiating Civil Surgeon, 1st class; **Surgeon-Major D. F. Barry**, Civil Surgeon, from Sitapur to Gorakhpur; **Surgeon-Major C. C. Vaid**, Civil Surgeon, from Kheri to Sitapur; **Surgeon-Major C. P. Lukia**, Civil Surgeon, from Shahjahanpur to Fyzabad; **Surgeon-Major J. C. C. Smith**, Civil Surgeon, from Bara Banki to Shahjahanpur; **Surgeon-Major G. A. Emerson**, Civil Surgeon, from Jaunpur to Jhansi; **Surgeon-Captain L. G. Fischer**, Civil Surgeon, from Budaun to Moradabad. **Dr. C. Banks, M.B., C.M., D.P.H.**, is confirmed in the Uncovenanted Medical Service, and his services are placed permanently at the disposal of the Government of Bengal.

NAVAL MEDICAL SERVICE.

Deputy-Inspector-General of Hospitals and Fleets Walter Reid, M.D., has been placed on the Retired List at his own request, with permission to assume the rank of Inspector-General of Hospitals and Fleets.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Charles S. Smith to be Surgeon-Major.

VOLUNTEER CORPS.

Rifle: 3rd Glamorgan: Surgeon-Lieutenant-Colonel J. G. Hall resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Corps on his retirement.

THE SEWAGE FARM AT ALDERSHOT.

In reply to a question recently asked by Mr. A. Morton in the House of Commons regarding the alleged sickness and mortality caused by the sewage farm at the North Camp, Aldershot, and an inquiry as to whether anything had been done to remedy the evils complained of, the Secretary for War said that it was not known that any cases of death could be attributed to the sewage farm in question, although it was a fact that the farm was in an unsatisfactory state. Mr. Campbell-Bannerman added that negotiations were in progress with the local authorities with a view to the provision of another sewage farm at a greater distance from the camp, but steps were being taken in the meantime to improve the present farm. Everybody agrees with the Secretary for War as to the very unsatisfactory state of the existing farm, and we can only hope that it is not intended to continue it for a moment longer than is necessary to provide a new site as a substitute for it. Although it may be quite true that a properly worked sewage farm is not productive of any disease—and the good health of the labourers and their families employed upon sewage farms and residing in their immediate vicinity may be cited in proof of this—it cannot be said that they are never a nuisance. It is difficult to ensure such a perfect system of working them under all conditions as invariably to prevent their being so, and we certainly think that where ground is available, as it presumably is at Aldershot, a sewage farm should be established at a reasonably long distance from all barracks and hospitals. We hope that this will be the case with regard to any sewage farm and works proposed to be established for a big camp like Aldershot.

THE DEFENCE OF CHITRAL.

The coolness, courage, and gallantry displayed by the medical officers who took part in the defence of Chitral form a decided refutation of the calumny that puts the army medical officer on a lower footing than his lay brother in arms. In times of war the rôle of the surgeon is to attend the wounded, but circumstances often compel him to act in the double capacity of fighting the human enemy as well as keeping at bay the enemy death. How well he has performed this double rôle is shown by the history of all modern campaigns and no better example of his coolness, combined with courage and presence of mind could be afforded than by that of the heroic feat performed by **Surgeon-Captain Whitchurch**, when, at the risk of his own life, he rescued **Captain Baird**, who with his last breath hoped that his gallant rescuer would not be forgotten. It was only natural that the dying captain should be grateful for the services rendered by **Surgeon-Captain Whitchurch**, but when almost without exception military men and civilians speak of the deed as one of the bravest of the century nothing less than the honour of wearing upon his breast the medal whose legend is "For Valour" can adequately reward

Surgeon-Captain Whitechurch. Of Surgeon-Major George Scott Robertson we have already spoken, and when the long-deferred Chitral honours are promulgated we trust that he will occupy a prominent place upon the list.

THE LATE SURGEON-COLONEL C. McD. CUFFE, C.B.

A telegram from India has, we regret to say, been received announcing the death of this officer, who held the post of principal medical officer at Allahabad, Bengal. He entered the army as an assistant surgeon in 1863, passed through its various grades, and was promoted to be surgeon-colonel in 1893. The deceased officer had taken part in much field service. He was principal medical officer of the Transkei column throughout the operations against the Galekas in the Kaffir war of 1878, he served throughout the Zulu campaign to the conclusion of the war, was mentioned in despatches, and received the Companionship of the Bath, and medal and clasp; he also served in the Burmese expedition of 1887-8 (medal and clasp).

THE RECONSTRUCTION OF THE MILITARY MEDICAL SERVICES IN INDIA.

This subject is apparently again under consideration and is being freely discussed at the present time in the Indian press. The late military expeditions and the financial needs of the Indian Government have no doubt given a fresh impetus to the matter, which is one that was discussed many years ago in the pages of THE LANCET. It is contended that there should be some sort of amalgamation of the medical services, and that the Indian Medical Service should consist of a military and a civil branch, separate and distinct from one another.

THE MEDICAL SERVICE AND THE WAZIRISTAN EXPEDITION.

General Sir William Lockhart in his despatches refers to the medical service in connexion with the late Waziristan expedition. He states that Surgeon-Colonel Spencer most ably administered his department in the field and recommends the excellent work that was done by him, his officers, and other subordinates for very favourable consideration. He also gives special prominence to the valuable services of Surgeon-Lieutenant-Colonel Bookey and Surgeon-Major Shearer.

Surgeon-Major-General C. E. McVittie, Indian Medical Service, has been awarded a good service pension.

Correspondence.

"Audi alteram partem."

"THE MIDWIVES REGISTRATION BILL."

To the Editors of THE LANCET.

SIRS,—The words of which I made use before the Select Committee of the House of Commons were these: "If the proposed class of midwives were established, what will probably be the result? There will be great interference with the practical training of students at such medical schools as that of St. Bartholomew's." The proposed class has not yet been established, and I venture to prophesy never will be in this country; but if it ever is, I can only hope that the slipshod attendance upon cases at present permitted by the Obstetrical Society will not be sanctioned. I believe that even now, if midwives at present certificated were compelled to honestly attend twenty-five cases, there would be interference with the supply of cases required, at all events at some of the large medical schools. As it is, a proportion of the twenty-five cases required are in some cases only seen when the pupil walks round the wards with the physician.

I have no intention of discussing the present Bill or any other Bill for the registration of midwives. The principle upon which such legislation is based is essentially a vicious one, and I certainly trust that our profession will be true to itself and insist upon the rejection of the principle involved. An interested body, in the shape of the Midwives Institute, has made a loud cry in the interests of humanity; but what has said *Nursing Notes* recently (the organ of that Institute)? "It behoves every midwife who cares for her old and honoured profession, and who does not desire to see it confused with the work of monthly nurses, to

give time and interest in supporting the Bill, with the principle of which many are already familiar." And yet Mr. Humphreys, one of the champions of this Institute, tells us that the Bill is intended to limit the practice of midwives to cases of a simple nature. I had not intended to publish at present what I believe to be the practical method of solving the problem of providing attendance for those lying-in women unfortunately situated; but as Mr. Flemming has got hold of the same idea, though he believes, apparently, in registration, I venture to send a copy of a draught scheme which I have had prepared for some time past. It can scarcely be called a scheme, but rather the outlines of one. Please use your discretion in publishing the whole or a summary of it.

I am, Sirs, your obedient servant,

Hatfield, June 2nd, 1895.

LOVELL DRAGE.

DRAUGHT SCHEME.

The conclusions arrived at from a study of the actual conditions of the problem point in the direction of decentralisation as opposed to centralisation. Further, they tend in the direction of the assertion that the evils to be dealt with are local and not general, and, therefore, that a measure giving local authorities powers to deal with conditions complained of in any part of the district, with discretion and latitude of power in dealing with them, is the measure most likely to give practical effect to the humanitarian views which have prompted the promoters of the legislation for registration of midwives to forward that proposed legislation by every means at their command. From the point of view which I have the honour of submitting, it appears certain that a measure affecting the whole community in the various ways which I have from time to time set out will not bear comparison with a measure intended to deal with such districts only as have been found, after competent inquiry into their actual conditions, to need such special treatment. Now the measure which will, it is believed, be most likely to attain the object in view must be based on the following lines:—

1. On complaint being made to the medical officer of health or directly to the district council by any persons that—(a) the women of any portion of the district are unable to obtain sufficient assistance at the time of their lying-in, or (b) if it comes to the knowledge of the medical officer of health that there have been cases of infective puerperal disease or death amongst lying-in women, caused by want of proper assistance, that it shall be the duty of the medical officer of health to make inquiries on the spot, and report to the district council.

2. If the district council are satisfied on the report of the medical officer of health that the women of the whole or any part of the district are unable to obtain proper assistance at such times, it shall be the duty of such council to forward to the county council the report of their medical officer of health and any decision at which they may have arrived.

3. If the county council are satisfied that some definite steps are necessary, it shall be their duty to cause inquiry to be made.

4. That such inquiry shall be conducted by a barrister assisted by the medical officer of health of the district, or such other registered medical practitioner as the county council may appoint.

5. That such barrister shall report to the county council (a) as to whether the women in the district reported upon are unable to obtain that assistance during the lying-in which is sufficient; (b) whether there have been an excessive number of deaths either from accidents or diseases connected with childbirth in the district; (c) whether it is necessary to provide the services of a nurse-midwife in the district; (d) whether there is any woman at present assisting in the district who would be suitable for acting as a nurse-midwife to that district if she were given a short training in a maternity hospital; (e) further, upon any special points connected with the subject which such barrister may consider to be necessary; and (f) sufficient power to be given to the barrister to call witnesses and to examine them on oath.

6. If the county council are satisfied that there are sufficient grounds for their interference, that it shall be their duty to provide for the needs of the lying-in women in their district.

7. That they shall base their action upon the lines of the present Poor-law system.

To the Editors of THE LANCET.

SIRS,—Whilst thanking you for the terms in which you allude in your issue of June 1st to the work of our deputation to the General Medical Council, there are two points in your leading article to which we desire to call your attention.

1. You suggest a doubt as to whether "the little more knowledge possessed by a woman of a few months' training, as compared with that of the woman who has had absolutely no training, constitutes a real danger to the community." Now this is perhaps the gravest question at issue and it is needful that our position be clearly stated. We say that the "little more knowledge possessed" is of the wrong sort, for whilst "nursing" is not taught to so-called "midwives," the use of poisonous drugs—such as ergot, opium, chloral—is suggested to them (as well as the management of abnormal labours); and, further, there is nothing to prevent the mistress of a brothel from entering herself for a course of lectures in which she is taught how to facilitate abortion. And we assert that this "knowledge" constitutes a real danger both to the health and morals of the community.

2. You minimise the importance of the objections to the certificate of the Obstetrical Society, which has been

approved of by the Executive Committee of the General Medical Council. Hitherto the Council has refused to sanction any certificate of competency issued by unauthorised bodies purporting to qualify in any branch of medicine, surgery, or midwifery. We freely acknowledge that the new certificate is a vast change for the better. All the same the question will arise, Is it not, now that it is "approved," a certificate of competency? Surely if a person holds a certificate of having passed an "examination in midwifery" approved of by the General Council of Medical Registration and Education the holder becomes *de facto* qualified in that "science and art," otherwise what is the use or intention of the certificate? New difficulties begin with this "new departure" on the part of the General Medical Council. The Act of 1886 suppressed diplomas in the separate branches of medicine. If the Council, however, sanctions the new certificate in "midwifery" (without qualification) does it not at once constitute a twentieth qualifying body? But further complications arise. The Parliamentary Bills Committee of the British Medical Association recommends the substitution of the term "midwifery nurse" for "midwife" throughout the Midwives Registration Bill, and our ever-active direct representative, Sir W. Foster, proposes that the General Medical Council do the same. The position, in the face of the new certificate, will be truly anomalous. For what can a person be who possesses an *approved* certificate of having passed in "midwifery" if she be not a "midwife"? and how can she be a "nurse" if she has had no training in nursing?

As general practitioners, we feel that the question is one which the public should determine. If the educated classes desire to palm off on their poorer sisters a midwife of three or four months' "education" (!) as capable of piloting them through the dangers of childbirth, we say it is a false philanthropy. The most skilled medical aid, male or female, should be available for even the poorest of mothers. Anything less than this constitutes a grave danger both to the health and to the morals of the community.

We are, Sirs, yours truly,

WM. HUGH HUGHES,

Chairman.

COLIN CAMPBELL

Hon. Secretary, Lancashire and Cheshire Branch Committee
of the British Medical Association.

Manchester, June 3rd, 1895.

"ADENOID GROWTHS IN CHILDREN."

To the Editors of THE LANCET.

SIRS.—I see that in your issue of June 1st Dr. McBride takes exception to my statement that the laryngeal stridor of young infants is often due to the irritation set up by adenoid growths in the naso-pharynx, and desires to know my authority for the assertion. The cases in question are rare and I do not profess to have seen many of them. Since connecting them in my mind with post-nasal vegetations I have only seen two, but in each of these cases the mucous membrane in the post-nasal region was not merely thickened but coarsely granular; and in one of them the end of my finger came in contact with a softish irregular lump which I took to be a small mass of adenoids. The children to the best of my recollection were three or four months old. That these vegetations are common in young infants I have satisfied myself by repeated observation, and that they are often congenital I feel sure. It is far from rare to find in an infant six months old the naso-pharynx blocked by a quantity of growths and to hear that the child had habitually snored in his sleep from the time of his birth. As to the mechanism of the stridor I prudently refrained from giving an opinion. Whether it be a spasm or a paralysis or something else I do not know. Probably it may be set up by widely different conditions. Dr. Lees has shown that it is sometimes due to a congenital malformation, for he has recorded a case in which the epiglottis was found to be folded upon itself in such a manner as to bring the ary-epiglottic folds close together and narrow the laryngeal opening to a mere pin-prick. Dr. Lees stated at the time that this was the fourth case of the kind he had seen; and Dr. Barlow tells me that he has met with similar cases. Had my paper been upon the subject of laryngeal stridor instead of upon that of adenoid growths I should have gone more fully into this question; as it was, I referred to it only so far as it bore upon the matter I was engaged

in considering. That the stridor may be put a stop to—sometimes, at any rate—by treatment of the adenoid overgrowth I stated on the authority of Dr. W. Robertson, who has published some interesting cases in which this treatment was successful. These cases seem to me to be conclusive as far as they go; yet I admit that they hardly warrant the inference that stridor associated with adenoid growths can always be cured by treatment directed to the naso-pharynx; for it is quite conceivable that post-nasal vegetations may coexist with laryngeal abnormalities such as Dr. Lees has described. Still, wherever these growths are met with in cases of stridor I think treatment should be directed to them, as it can do no harm, and Dr. Robertson's experience is very encouraging.

I am, Sirs, yours truly,

EUSTACE SMITH.

Queen Anne-street, Cavendish-square, June 5th, 1895.

MEMORIAL TO THE LATE SIR EDMUND LECHMERE, BART., M.P.

To the Editors of THE LANCET.

SIRS.—There are many friends of the late Sir Edmund Lechmere, M.P., who are aware how much he interested himself in the establishment of an ophthalmic hospital at Jerusalem, under the management of the Order of the Hospital of St. John of Jerusalem in England, and who would be glad to subscribe to a fund for placing that hospital on a permanent basis as a memorial of the services rendered by him in that and other philanthropic work. This proposal, I am permitted to state, has the entire concurrence of the Grand Prior of the Order, His Royal Highness the Prince of Wales, and as the chairman of the committee appointed by His Royal Highness I should be glad, through your columns, to invite support to the scheme.

The British Ophthalmic Hospital was established at Jerusalem in the year 1881, and the magnitude of the work may be estimated by the simple statement that there is no other hospital in Palestine dealing with the numerous diseases of the eye so prevalent in that climate, so that people come from all parts of the Holy Land to seek the restoration of sight or to obtain relief from suffering. The report furnished by the medical officer in charge for the last three years is as follows:—

Applicants for admission	6068
In-patients	2379
Out-patients, new cases	25616
Out-patients, total cases	69379
Operations	4823

It is sad to record that during the last year 905 applicants were turned away because they could not be treated with any hope of success as in-patients, and there were neither beds in which to receive them nor funds to pay for their support. The hospital stands alone among the charitable institutions of Jerusalem in preserving an attitude of absolute impartiality among the holders of different creeds, and in admitting to its benefits on equal terms Christians, Jews, and Mohammedans, not only without any attempt to make proselytes, but with full security for religious freedom to them all. The present annual subscriptions are inadequate for the maintenance of the hospital, which, even in its present state of efficiency, requires an annual income of at least £900. This appeal is to raise an amount necessary to endow the hospital, and thus not only to maintain but to widen the sphere and to increase the scope and usefulness of a charity which has won for itself a first place among the institutions of the Holy Land.

I am authorised to add that Katherine, Lady Lechmere, will contribute £1000 as a donation to the fund. Donations will, unless otherwise directed, be acknowledged in your columns, and should be sent to the honorary secretary, Mr. R. Gofton-Salmond, 73 Cheapside, E.C., or to the account of the hospital at the London and Westminster Bank.

I am, Sirs, yours truly,

EGERTON OF TATTON.

St. James's-square, S.W., June, 1895.

"DR. NIVEN ON JEWISH MORTALITY."

To the Editors of THE LANCET.

SIRS.—I shall be obliged if you will allow me to make some corrections in the report of the remarks which I made

at the annual meeting of the Jewish Ladies' Visiting Association, and which you have done me the honour to insert in THE LANCET. I did not say that the Jews insisted on getting pure milk, but, on the contrary, regretted that they did not bestow a care on their milk-supply similar to that which they gave to their meat-supply. It is not the case that the death-rate in the Jewish quarter is in any case not more than half that of the poorer districts of the city generally, and I did not say so. What I said was that it was not more than half the death-rate in some of the poorer adjoining districts. I did not say that the Jewish people were exceptionally clean, except as regards the weekly ablutions which their law prescribes. What I said was that the very poorest class of Jews compared not unfavourably with the corresponding class in neighbouring districts, but that, on the other hand, there was reason to believe that the industrial classes rather higher in the scale were more slovenly in their habits than the corresponding class of English people—that is, so far as their houses and yards are concerned. While I believe that there is much to be learned from the Jewish people, and not a little good in their customs which might be extracted by people who can free their minds from cant and prejudice, one must guard oneself against the imputation of remarks which are not well founded.

I am, Sirs, yours faithfully,
Manchester, May 31st, 1895. JAMES NIVEN.

SEWAGE EMANATIONS AND ENTERIC FEVER.

To the Editors of THE LANCET.

SIRS.—Although it is a generally accepted fact that sewage emanations may give rise to enteric fever, it is comparatively seldom that one has such positive evidence of the direct relationship between the two as the following case affords. In the Finchley district about eight weeks ago a house in a good sanitary condition, and showing from my register a "clean bill" so far as any previous visitation of zymotic disease among any of its occupants was concerned, became insanitary by reason of a sudden stoppage of the drain and the consequent bursting of the joint with the soil pipe. The result was that every time the upstairs water-closet was used the excremental matter escaped at this leak, accumulated under the "footings," and after a time appeared above the cellar floor, where it was discovered standing to a height of about an inch. Before the condition could be rectified the odour was more especially complained of by one of the occupants of the house, who occupied a bedroom situated over the escape, and in this particular room the odour of the sewage made itself very manifest, more especially at night time. The individual had previously enjoyed immunity from those conditions that have ever been shown to have their origin in such emanations, but in eighteen days he was laid up with enteric fever. My letter would be too long if I went into the grounds that I have for believing that it is highly improbable that the patient contracted the disease away from the house.—I am, Sirs, yours faithfully,

HENRY KENWOOD,

Medical Officer of Health for Stoke Newington, and
also for the Finchley District.

Stoke Newington, N., June 1st, 1895.

"THE CARE OF YOUNG IMBECILES."

To the Editors of THE LANCET.

SIRS.—In your annotation under the above heading in THE LANCET of May 25th you mentioned that ample and satisfactory means in our highly organised social fabric for dealing with the defective at a comparatively early stage do not exist in any widespread or general sense. To the ordinary medical practitioners opportunities are not afforded for obtaining knowledge of abnormalities in institutions, but the writings of Warner, Shuttleworth, Strahan, Beach, and others give full instructions how to proceed with cases at this particular stage. In dealing, however, with the great vital question we have lost sight of the principles which Connolly advocated more than thirty years ago, which, had he lived, would in all probability long since have been in voluntary coöperation with State medicine. He maintained that the moment the defective are born the moulding ought to begin. The enormous amount of positive proof of the successful management at this early stage of the

enfeebled cannot for the benefit of humanity in general be too often reiterated. Day and night the family medical attendants are brought into the closest relations with the domestic circle. Their frequent visits afford ample opportunities of acquiring minute details of the family and personal histories, details which are of vast importance as adjuncts for dealing with abnormalities in infant life. This thoroughly true work of the practitioners of medicine is not sufficiently entertained. When much thought, energy, and guarded level-headed care are bestowed on these matters it is really marvellous how angularities, peculiarities, and other weaknesses the prodromes of thieving, madness, and suicides can be almost obliterated before the children reach the more unyielding and callous stage. These statements on my part are not mere theories deduced from inaccurate facts or doubtful statistics, but are sought out from the experience of years which has made a written and sealed impression on my mind. So much has it impressed me that I brought the subject forward in Rome at the Medical Congress, and before other societies too. You, Sirs, were also good enough to publish a letter of mine bearing on it in THE LANCET of July 28th, 1894. Still, notwithstanding all our efforts, all our methods of organisation, and the compiled and reiterated literature, this sad fact remains that suicides, discontent, and mental miseries are increasing, and insanity is not diminishing. Is the young practitioner to learn his work in the treatment of these phases of the abnormal in infant life, unhelped as many of us in the past have had to do? Is he also to learn too late by the bitter experience of blundering how grander results might have been gained by him had the State put into his hands a code which would have invested him with authority? Why does the State still hold back in this particular? The progress of society, the hope of humanity wait for its intervention. Let the State strike the hammer of legislation on the anvil of conviction and place in the hands of those whose first medical work is among children a supplied system of general laws with which the many-sided mischiefs of infantile life can be combated.

I am, Sirs, yours faithfully.
Londonderry, June 1st, 1895. WALTER BERNARD.

MEDICAL CERTIFICATES IN LUNACY.

To the Editors of THE LANCET.

SIRS.—A few days ago I was requested to go to London to see a relative who was suffering from acute mania. The medical man who was attending her considered it necessary that she should be placed in a home for the treatment of mental diseases, and at his suggestion the second certificate was signed by a medical man who had previously attended the lady.

As under the new Lunacy Act I was compelled to seek the assistance of a magistrate I applied to one living in Kensington, in which district my relative resided. After I had explained the case the magistrate told me that he only filed in these orders after the cases had been seen and certified to by his own medical attendant. This, I told him, I did not think necessary, as the patient had been seen and certified to by two well-known practitioners in London, and I did not see the necessity for putting the patient to extra expense, and also I considered that it would be discourteous to the medical gentlemen who had already seen the case to call in a third opinion.

The magistrate said he was not compelled to fill up the papers, and as he made it conditional on his own medical attendant seeing the patient I left and applied to another magistrate, who signed the order without making any stipulation. I should like to have your views, firstly, as to whether you consider a magistrate is justified in refusing to fill up the papers as required by the new Lunacy Act unless he can show that there is irregularity or a want of compliance with the law; and, secondly, whether it is not somewhat irregular, and going beyond the requirements of the Act, for a magistrate to insist upon a third opinion, that opinion being given by his own medical attendant.

I am, Sirs, yours faithfully,
Cheltenham, May 24th, 1895. ALEXANDER INGLIS, M.D.

* * This is a case to which the attention of the Lord Chancellor should be called. The medical certificates accompanying the petition are by law equivalent to evidence

on oath; and, though a justice has the right to postpone the inquiry if he thinks there is reason to doubt the *bona fides* of those signing, the refusal of the justice in question to sign until his own medical attendant had seen the patient was, we think, certainly *ultra vires*. Section 6 of the Lunacy Act does not seem to allow the justice to give any such reason for refusing to sign.—ED. L.

INSOMNIA AND CHLOROBROM.

To the Editors of THE LANCET.

SIRS,—Professor Charteris' admirable paper in THE LANCET of May 25th is as interesting as it is edifying. The treatment of insomnia, like that of every other diseased or unhealthy state, should be based on the pathological condition, the alteration in function or structure on which it depends; but chlorobrom cured Professor Charteris' patient without, so far as I can gather, any reference to the cause or origin of the insomnia. Chlorobrom is such a valuable medicine that, irrespective of its nature and constituents, it cannot be too widely known how and where it can be readily procured for cases of emergency. It is sold in four-ounce bottles bearing a trade-mark, and a large pink label, commonly called a chemist's label, is affixed to each bottle, on which is conspicuously printed: "This preparation is recommended by Professor Charteris of Glasgow University as an effective and safe hypnotic, giving excellent results in all cases of insomnia and sea-sickness." The name of the worthy professor so boldly printed on the label is so unmistakable, and such a source of comfort and security to both prescriber and patient that the efficacy of the medicine is augmented by the confidence it inspires.—I am, Sirs, yours faithfully,

D. MACKINTOSH, M.D.

Alexander-square, S.W., June 3rd, 1895.

"MICRO-ORGANISMS IN THE HEALTHY NOSE."

To the Editors of THE LANCET.

SIRS,—In your report of the discussion on the above subject at the meeting of the Royal Medical and Chirurgical Society on May 28th there are several inaccuracies which might be so misleading that I venture to ask for a small space to correct them. Dr. Semon did not say that "the fact that so few bacteria had been found was astonishing." His words had an entirely opposite meaning, for he remarked that our results had agreeably surprised him, since our experiments—while contradicting the majority of previous experimenters on the subject—were quite consonant with his own clinical experience. The sentence where he is quoted as saying that "the nose was anatomically antiseptic" contains a printer's error in not reading "automatically"—the expression employed in the original paper. Your report as to Dr. Semon's referring to the removal of adenoid growths in children being "the then popular operation" might be very misleading. He referred to it as the very frequent operation—not only a common operation "years ago," but also at the present time. In my own reply I never said that "Sir Joseph Lister used to point out that empyemata, which discharged through the bronchi through which the patient breathed very seldom, became septic, which he ascribed to the ciliated epithelium, and he compared this with what took place when the empyema communicated with the air through a fistula." (1) Fortunately this quotation is so evidently self-contradictory that few readers will fail to see its inaccuracy. I said that Sir Joseph Lister was in the habit of pointing out that when an empyema communicated with a bronchus, through which the patient breathed freely, thus allowing the cavity to communicate with the air, the pleural contents did not become septic nearly so readily as when the cavity communicated with the external air through an opening in the chest wall. This difference of result he partly ascribed to the action of the ciliated epithelium in the former case. These corrections are made with the authority of Sir Joseph Lister and Dr. Semon, who are both anxious that I should see that they are made public.

I am, Sirs, yours faithfully,

ST. CLAIR THOMSON, M.D.

Queen Anne-street, W., June 5th, 1895.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Prevention of Cruelty to Children.

THE citizens of Liverpool are justly proud of the fact that the local Society for the Prevention of Cruelty to Children was the first of its kind. This, however, is somewhat discounted by the answer to the question, What led to the formation of the society? For several years past the condition of many children in the streets and at their own homes was a painful fact known to medical practitioners in the district, to clergy, ministers, and police officials, but to very few others. Travellers from America and the Continent, and even visitors from neighbouring towns have been appalled at the bare-footed, ragged condition of the beings variously termed "wails and strays," "gutter children," and "street arabs." Much of this was deliberate cruelty, the children being turned out in the streets in this state to excite sympathy and earn money for their unnatural parents. The Liverpool Society for the Prevention of Cruelty to Children has now completed its twelfth year of work, and the following details are given in the annual report just issued. It was the earliest society of the kind in Great Britain. Owing to the generosity of a citizen (the late Mr. William Cliff) it has possessed a commodious shelter in a central part of the city, where the secretary, Major Leslie, and his efficient staff carry out the operations of the society. Sometimes there are as many as sixty to sixty-five children sleeping in the shelter. The society receives and shelters children suffering from violence or neglect or in dangerous surroundings. It investigates the cases, listens to and counsels the parents or persons in charge, and restores the children, watching the cases afterwards. In the more serious cases it prosecutes the offenders. It endeavours to check that standing disgrace of Liverpool, the employment of children in begging and selling in the streets. The society works in thorough accord with the police, the School Board, and the various societies and institutions of every kind for the reception of children which are scattered over the city and suburbs. For the last six years the average number of children dealt with has been 2100, and a marked improvement has taken place, though much remains to be done.

"The Prevention of Overlaying."

Referring to the annotation in the last issue of THE LANCET, it may be remarked that in not a few instances coroners' juries have returned verdicts of manslaughter against parents who have gone to sleep in a drunken state with an infant in the same bed. Unfortunately the result has not been such as to encourage the repetition of such verdicts. In 1893 a drunken mother was convicted and sentenced by Mr. Justice Day to three months' hard labour. The course which legislation should take is indicated by the result of Prussian legislation as described by Casper. "According to a former penal code mothers and nurses were forbidden under pain of imprisonment to have children under two years old in bed with them." As might have been expected, contraventions of this peculiar statute were of frequent occurrence, and any attempt to enforce a similar one in the United Kingdom would certainly share the same fate. The new penal code of Prussia no longer recognises this offence; but the Public Prosecutor institutes proceedings in all cases of death from neglect. There can be no doubt that this might be done with a reasonable hope of success in all cases where drunkenness could be proved. It must not be forgotten that poverty is, in many cases, the reason why there is no separate cot for the infant, and that in this respect there is work for philanthropists.

A Female Drunkard's Career.

The three leading local papers of the 3rd inst. contain paragraphs variously headed "Death of a Notorious Liverpool Character," "Death of a Well-known Character in Walton Gaol," and "Death of a Notorious Police Character." The paragraphs vary in length from thirty-two lines to nearly half a column. What bitter irony is contained may be judged from the following facts. The deceased was about fifty years of age and had been before the magistrates on 277 occasions, 93 being acquittals and 184 convictions. It may interest physiognomists to learn that she looked somewhat older than her actual age, was of a wiry and powerful build, possessed a thin, angular, and irresistibly quaint face,

and had a voice which, though ordinarily as hoarse as the cry of a corn-crake, could when necessary be as shrill and ear-splitting as a "Clan liner syren." Her frequent appearance before the bench was mostly on charges of being drunk and disorderly; she was often guilty of violence, having shown her resentment against the magistrates by the discharge of missiles—huge pieces of stale bread, pieces of glass, and even her crutch. Quite recently Mr. Sampson, the city coroner, who presides as magistrate in the "drunkards' court," had a narrow escape from a dangerous blow, the crutch having been hurled at him as the prisoner left the dock. Her last appearance was on the 24th ult., when she was charged before the stipendiary magistrate with stealing a shawl, and was fined 5s. and costs, or a month. She chose the latter, and should have come out of prison on the 31st; but she became ill, was removed to the infirmary of the gaol, and died on the following day. An inquest was of course held, and a verdict of "Death from natural causes" was returned.

The Magistrates and Crimes of Violence.

In contradistinction to the case reported in the Manchester letter in THE LANCET of last Saturday it is satisfactory to note here that a very wholesome result has followed the action of the local magistrates in dealing with all cases of assault. Those involving such serious personal injury as the loss of an eye would be certainly sent to the assizes, judges having power to award penal servitude for such savage conduct. Where the injury is less serious imprisonment for a longer or shorter period is the general rule, especially in assaults on the police, the "roughs" having been frequently warned by the stipendiary magistrate that he has power to give six months' hard labour for wounding or serious assault. The lay magistrates, moreover, are by no means disposed to regard assaults leniently, and the total number of persons charged with assault during 1894—2530—will not appear excessive in such a city as Liverpool, while there is every probability of its being considerably reduced this year.

The Liverpool Northern Hospital.

At the meeting of the City Council on June 5th a resolution was carried granting to the trustees of the Northern Hospital two sites adjacent to the present hospital consisting respectively of 630 and 1545 square yards, and also to give £10,000 to the funds of the hospital. The new hospital is to be built by the David Lewis trustees and will be on a greatly enlarged site, including part of that now occupied by the present building. The hospital, which was the second one established in Liverpool, was founded sixty years ago, and the present hospital was built in 1844. It is needless to remark that it is now totally out of date and wholly inadequate to meet the demands made upon it; while it is expected that the new hospital will not only have every modern improvement, but will be fully capable of meeting any future demands.

June 5th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Professor Fraser at the Edinburgh Royal Society.

AT the Edinburgh Royal Society on June 3rd Professor Fraser made an interesting communication regarding an important investigation he was undertaking on the venom of the cobra and other serpents. He had been engaged in this work since 1889, and had experimented with venom from many of the poisonous snakes in Asia, Africa, and Australia. He had separated the venomous principle and obtained it in crystalline form and was able to determine the lethal dose of the crystalline poison in various of the smaller quadrupeds. He gave a historical account of the belief that human beings could resist the venom of serpents, and also stated that venomous serpents were protected from the effects of bites of both their own species and of others. It was largely with a view to investigate this side of the subject that he had undertaken the experiments. After ascertaining the minimum lethal dose for an animal he proceeded to administer a succession of graduated doses, with the result that rabbits had received by subcutaneous injection as much as ten, twenty, thirty, and even fifty times the minimum lethal dose without manifesting any obvious symptoms of poisoning; they even increased in weight and were alive and well. The rabbits had

received as much venom as would kill fifty non-protected animals of the same size, and it was incidentally ascertained that the protection lasted for a considerable time. Having thus succeeded in producing a high degree of protection in animals, he collected the blood serum of those animals for the purpose of testing its antidotal powers. Experiments were described which he held clearly established that the blood serum of animals protected against large lethal doses of venom was able, in varying conditions of administration, perfectly to prevent lethal doses of the most poisonous of serpents from producing death in non-protected animals. He promised further experiments with a view to the effect in man, and also to discover the constituents by which the antidotal effects were produced. There was a large meeting of the society, the members very heartily manifesting their appreciation of the importance of this communication, and it is needless to dwell upon the far-reaching importance of this discovery should the various steps of it be confirmed, which there is every reason to believe they will be.

The Lord High Commissioner and the Marchioness of Breadalbane.

The Lord High Commissioner and the Marchioness of Breadalbane have, during their stay at Holyrood Palace for the meetings of the General Assembly of the Scottish Church, paid their usual visit to the medical charities, including the Royal Infirmary, the Hospital for Incurables, and the new Deaconess Hospital.

The Habitual Offenders Committee.

In the report of the Scottish Departmental Committee appointed by the Secretary for Scotland the question of habitual inebriates is dealt with *inter alia*. The committee recommend that the powers of the Inebriates Act should be considerably extended and that provision should be made for the compulsory committal to a retreat of those proved to the satisfaction of the sheriff to be habitual drunkards. The application for such committal, it is proposed, may be made either at the instance of the friends of the person concerned or by the procurator-fiscal acting in the public interest. It is also suggested that power should be given to employ the property of an inebriate for his own support, and that in the absence of available funds he may be confined either in a "labour retreat" or in a poor house for a period not exceeding two years. Another proposal is that the term "habitual drunkard" shall be extended to include persons reduced to the condition it describes through the abuse of opium and other drugs as well as alcohol. Amongst the signatures to the report are those of Sir Charles Cameron, M.P. (chairman), Dr. Robert Farquharson, M.P., and Dr. J. F. Sutherland, the latter of whom acted as secretary to the committee.

University of St. Andrews.

The annual statistical report of the University to the Secretary for Scotland, just issued as a Parliamentary paper, contains the following information with regard to the emoluments of the professors and lecturers in the Faculty of Medicine. Practice of Medicine (J. Bell Pettigrew, M.D.), £368 7s. 2d.; Chemistry (Thos. Purdie, B.Sc.), £299 2s. 3d.; Natural History (D'Arcy W. Thomson, B.A.), £425 8s.; Botany (Patrick Geddes, F.R.S.E.), £222 11s. 4d.; Anatomy (A. Melville Paterson, M.D.), £408 16s.; Physiology (E. W. Reid, M.B.), £386 9s.; Chemistry (Percy F. Frankland, F.R.S.), £459 12s. 4d. With the exception of the two first mentioned the work of these chairs is conducted in University College, Dundee. During the year eleven gentlemen have been admitted to the degree of M.D. Amongst recent benefactions is the residue of an estate estimated at £35,000, and bequeathed to the college at Dundee.

Glasgow University.

It is announced that a gentleman—whose name is not divulged—has offered a considerable sum of money—not less than £10,000—to found a chair of Political Economy in the University. This will come as grateful news, more especially to those who have recently been taking steps to secure adequate representation of the subject of political economy in the university of Adam Smith. In addition to this prospective vacancy the University Court will have shortly to make appointment to two other chairs—the professorship of Divinity vacated by Dr. Dickson, and the Professorship of Logic which was held by the late Dr. Veitch. The Victoria University has conferred the honorary degree of Doctor of Science on Lord Kelvin, from whom, according to Professor

Welkins, the first suggestion for the foundation of that University originally came. The final examinations for degrees in medicine and surgery of the Glasgow University commenced on the 5th inst. This is the last year for candidates who commenced to study under the four years curriculum, and the rush which took place before the five years system became compulsory is shown by the large number of entrants on the present occasion. The number of candidates is 194.

Glasgow Public Dispensary.

The annual report of this institution shows that the number of consultations during the year has been 3706, an increase of 554 on the previous year. Two new departments have been recently added, one for diseases of the eye and one for nervous diseases. A small ward for the reception of patients has also been opened during the year. One of the principles of the dispensary is that each patient pays a small sum, and to this feature Professor McKendrick drew special attention in seconding the adoption of the report. The treasurer's statement shows a balance in hand of £42 3s. 8d.

Glasgow Health Committee.

A subcommittee has been appointed to take action in reference to the Factory and Workshops Bill at present before a Select Committee of the House of Commons. It is contended that if passed in its present form the Bill will produce considerable confusion between the Government inspectors and the local sanitary authorities, and will inevitably lead to friction in the administration of sanitary and factory legislation. Steps will therefore be taken to place the views of the committee before the House of Commons. The committee of the town council on cholera precautions has ordered the repetition of the measures taken last year in the form of cleansing outhouses, ashpits, &c. These and other active sanitary operations seem to be called for by the extent to which diarrhoea has been prevalent in the city for the last week or two. The number of cases of small-pox has considerably decreased; there are now only twenty-four patients in the hospital.

The Purification of the Clyde.

It is reported that one effect of the sewage works opened some time since in the east-end of Glasgow has been to produce a distinct improvement in the condition of the Clyde. Plans for dealing with the sewage on the north of the river have now been completed, and the authorities have under consideration a scheme for application to the south side, so that it is expected that the necessary steps may be taken for submitting proposals to Parliament at the beginning of next session.

Glasgow Maternity Hospital.

Dr. P. McBride and Dr. Patrick have been appointed house surgeons in place of Dr. Cumming Grant and Dr. Jameson, whose term of office has expired.

Faculty of Physicians and Surgeons of Glasgow.

Dr. Robert Jardine, and Dr. R. M. Buchanan, having passed the necessary examinations and been duly elected, have been admitted as Fellows of the Faculty.

The Queen visits a Medical Staff Corps in Camp.

The Aberdeen Volunteer Medical Staff Corps went into camp at Birkhall, near Ballater, on the 30th ult. Besides officers there were one first-class and two second-class sergeants, five sergeants, and over ninety rank and file. On Friday afternoon the Queen drove from Balmoral Castle, her Highland residence, about seven miles from Birkhall, and inspected the camp. Some of the juvenile Princes and Princesses were delighted at the novelty of camp life. Among those who accompanied the Queen was Mr. Profeit, L.R.C.S. Edin., Her Majesty's Commissioner at Balmoral. Her Majesty drove along the lines, showing interest in the "wounded" lying bandaged on the stretchers and in the soldierly ranks of the others standing at attention by their side. Sir Fleetwood J. Edwards presented individually to Her Majesty Surgeon-Captain Macgregor, Surgeon-Captain Riddell, and Quartermaster De Lessert. Surgeon-Lieutenant Urquhart was also presented to the Queen. H.R.H. Princess Beatrice and suite were present at the inspection on Saturday. The men returned to Aberdeen on Monday.

Clearing out the Slums in Aberdeen.

Some time since Mr. Sheriff Brown held a local inquiry as to an application by the Aberdeen Town Council for sanction of a scheme under the Housing of the Working Classes Act for

dealing with an unhealthy area in the east end of the city, bounded by Exchequer-row and Ship-row. The Secretary for Scotland, having perused the evidence and considered the learned Sheriff's report, has now granted the order applied for. This scheme proceeded on a representation by Mr. Matthew Hay, medical officer of health of the city of Aberdeen. The area embraces three narrow courts and the principal portions of two others. It measures about 3124 square yards, or two-thirds of an acre. Dr. Hay found that it contained 98 dwelling-houses, 5 common lodging-houses, one house let in lodgings, 13 shops and stores, and 2 offices. The total population of the area at the date of his report was 508. Of the occupied dwelling-houses, 39 were one-roomed, 43 were two-roomed, and 16 had three or more rooms. The larger houses mainly fronted Castle-street and Ship-row. Dr. Hay reported this area, with only 6.3 square yards to a person, as the most overcrowded in the city and as having an exceptionally high death-rate, equal to 28 per 1000 per annum, against 19.9 for the city generally. It was impossible to adequately light and ventilate the individual dwelling-houses or to find space for sanitary conveniences. The town council have therefore acquired the buildings. The best of them—i.e., those on the margin which front public streets—will not be removed. The others will be taken down, but it is not yet quite settled whether to run part of a new street through the area or leave an open space or children's playground. The total cost of the properties acquired will be £25,776; those available for re-sale, £10,950; and the net cost of the scheme, £14,826.

New Bursaries at the University of Aberdeen.

The Aberdeen Highland Association have agreed that a bursary of £10 should be given to a student attending the art classes at the University of Aberdeen, and another of £10 to a student of medicine, both tenable for one year.

Typhoid Fever in Inverness-shire.

Dr. Ogilvie Grant, the medical officer for the county of Inverness, gives in his recent report an instance of cowardice, the result of superstitious fear, which occurred in connexion with an outbreak of typhoid fever in a remote part of the country. The houses in the neighbourhood of the infected district were all deserted, and no native could be persuaded to attend upon the sufferers or even to bury the bodies of those who died. The proverbial courage of the Highlander is not always proof against the mysterious terror associated with anything in the shape of "fever."

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Belfast Society for Providing Nurses for the Sick Poor.

The report presented to the annual meeting of this society, held in Belfast on May 24th, showed that, owing to the increase in the population, two new districts have been added, and for one of these a lady has given £100 to maintain a nurse for one year. Belfast is increasing at the rate of 10,000 each year, and yet for some of the districts with a population of over 44,000 there is only one nurse. The subscriptions last year were £876 11s. 3d., while there is an income of £253 16s. 4d. from funded donations.

The New Lunatic Asylum at Purdyburn.

I understand that it has been decided to make such structural alterations in the old mansion at Purdyburn as will render it capable of affording accommodation for seventy-five inmates. There are 300 acres on this fine property, which is situated in a very healthy district. The new County Antrim Asylum at Holywell, which is at present in course of construction, will be ready for the reception of patients in about two years. At the present time, in the Belfast asylum there are 260 inmates over and above the number for which there is accommodation. Belfast has the most limited asylum accommodation of any city in the United Kingdom. At Purdyburn increased buildings can easily be built.

Downpatrick Water-supply.

Mr. Cotton, who presided at the inquiry held at the instance of the Local Government Board into the alleged defects in the new water-supply at Downpatrick, has just issued his report. He thinks that, as regards the efficiency of the works for the supply of a sufficient quantity of water at all times, the inhabitants of Downpatrick

need not be under any apprehension. The cause of the defective quality of the water in the reservoir is due, he thinks, to peaty water from the catchment area, and to the bed of peat or bog under the water area. The quality is further deteriorated in the distribution pipes of the town by the effect produced by water laying in pipes newly laid and coated as usual; but this effect is only transient. Mr. Cotton recommends as remedies: (1) covering the bog in the reservoir, and (2) providing filter-beds, both of which had better be undertaken without delay. As to the depth of covering, he would leave this open until the progress of the work enables the engineers to form a definite opinion on the point. He recommends sand filters of sufficient area and depth of filtering material. Downpatrick is now depending for its supply of water mainly on pumps.

The Ligoniel Sewerage.

At the meeting of the Belfast board of guardians held on May 28th the committee appointed to inspect the Fourth river and its tributaries reported that the first offensive place was a large excavation in a field near the centre of Lower Ballysillan, into which the sewerage of at least fifty houses flowed; it was also a receptacle for dead animals, and the smell from it was unbearable, and they believed it was the cause of a great deal of sickness. The overflow from it ran in an open drain, the water being black, and it was reported that cattle drank from it. The committee concurred with the inspector, Dr. Clibborn, that the severe outbreaks of typhoid fever which had occurred in Lower Ballysillan were chiefly caused by the insanitary state of the district of which the stream in question was an important element, and they recommended that the board should proceed to have a complete scheme for the sewerage of Ligoniel and Lower Ballysillan carried out, and they suggested that until this was done the owners of cattle in the fields referred to should be required to supply the cattle with pure water, and by erecting fences to prevent the cattle from drinking the sewage matter. Another member of the board reported that he examined the river between the point at which the committee left off and where it joined the river Blackstaff at Broadway, and at several places there was evidence that dairy cattle drank from this polluted stream. It was also stated by another guardian that cases of sickness could be traced from house to house where milk had been used in those districts where pollution of the water existed. It is thus evident that there is a nuisance in the form of an open sewer both within as well as without the city boundary. After this report had been considered a very influential deputation representing the large majority of the ratepayers of Ligoniel appeared before the board of guardians, and suggested that instead of launching a large and expensive sewerage scheme at present they should adopt a plan of purification by chemical means (alumino-ferric) until the neighbourhood had still more increased, when a large and complete system, taking in the entire watershed, could be developed and carried out. The deputation said the cost of this plan would be small, and they asked the guardians to collect a small rate—say, 3d. in the pound—over the district to cover the expenditure. It seems that in the district, at some bleach works, the chemical plan has been tried on bad putrid water with great success. It was finally settled that the committee in charge of the Ligoniel sewerage scheme should meet together with the deputation and report to the board.

Rabies in Belfast.

Two people who were bitten by a dog (certified to be suffering from rabies) at Newtownbreda have been sent by the Belfast board of guardians to the Pasteur Institute, Paris, for treatment.

The Supply of Water to Belfast.

The amount of store-water is greater at present than at the same time last year, there being six months' supply in the reservoirs, but as the city is increasing so rapidly, and as there is considerable loss by evaporation in warm months, the ratepayers have been warned not to be wasteful. In the meantime the Mourne scheme, which will give an inexhaustible supply, is being proceeded with. No. 3 Contract of this scheme has been accepted for £139,746 13s.

Flat-roofed Houses in Belfast.

A new departure is about to be taken in Belfast by the erection of houses with flat roofs. At a recent meeting of the Improvement Committee of the city corporation plans were put before them for such houses, and before coming to a conclusion they instructed the officials of the Surveyor's

Department to visit such houses which have been fitted with these roofs, and as a result of their report it has been decided to allow such style of houses to be erected. These flat roofs are made of a bituminous, horn-like, and elastic substance which becomes in time as hard as metal, and is without seam or joint and is impervious alike to snow, water, or dust. The walls being carried up above the roof, the space thus formed can be utilised as a garden, playground for children, or for any other useful or ornamental purpose.

Rainfall in May in Belfast.

In the Belfast district May has been a phenomenally dry month this year. Only 0.31 inch fell, while in 1894 it was 3.30 inches. There were six days on which rain fell in May, 1895, while in 1894 there were twenty. The total rainfall for the present year is 11.23 inches, as against 17.36 last year. The country is becoming parched through the want of rain, and unless it falls soon hay will be very short, and turnips and flax (a very important crop in the north of Ireland) will be much below the average yield.

The Strangford Lough Boating Accident.

The body of the older of the two boatmen was found floating on Strangford Lough on Saturday.

The Armagh Government Board Inquiry.

The result of this inquiry is to transfer from the County Armagh Grand Jury to the Armagh urban sanitary authority the jurisdiction with reference to roads, bridges, footpaths, &c. within the township. The matter will be considered at the next assizes, and should assent be obtained the order will be made and sent to the Irish office to be introduced into Parliament, but it will probably not be confirmed until 1896. At a meeting of the Armagh town commissioners held on June 3rd it was decided to approve of a new sewerage scheme suggested by Mr. J. F. Peddie, C.E., the estimated cost of which is £8562 2s. 2d., exclusive of law, engineering, wayleaves, and other contingent expenses. It was also arranged to apply to the Board of Works for the loan of £10,000 to carry out this sewerage scheme.

Cork Societies' Medical Officers' Indemnity Fund.

The following additional subscriptions have been received by the treasurer, Mr. D. D. Donovan:—Dorset and West Hants Branch, British Medical Association, £3 3s.; South Wales and Monmouthshire Branch, £5. The council of the Incorporated Medical Practitioners' Association have forwarded £5 to the Indemnity Fund, and have promised to aid in every way they can the Cork medical men in their contest with the clubs.

The Proposed Dissolution of the Millstreet Union.

The proposal of the Millstreet board of guardians to dissolve the union and amalgamate it with adjoining unions has met with anything but universal approval in the district. A large public meeting has been held, presided over by the Very Reverend Canon Griffin, P.P., chaplain to the workhouse. The reverend chairman stated that he had carefully examined the financial aspect of the question, and was convinced that the amalgamation would not result in lessening local taxation. In support of that view he pointed out amongst other things that the existing officials would be entitled to substantial pensions to be paid from the rates. But he said what mainly concerned him and all of them was the inconvenience likely to be caused to the sick and the poor by conveying them in many instances long distances to the workhouses of the other unions. "Christ said that the poor would be always with us, but the present guardians of Millstreet Union think and act differently. They would banish the poor from our midst to remote towns where their hearts would never be gladdened and their faces brightened by the welcome visit of a dear relative, by the look from kindly eyes, or the touch of a loving hand." A series of resolutions were adopted and a petition to the Local Government Board was numerously signed, asking that Board not to accede to the guardians' request.

June 4th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Penetrating Wound of the Bladder through the Buttock.

A MAN standing erect received a knife-thrust in the buttock, with the result that shortly afterwards the urine voided

contained blood, and two days later urine escaped through the wound.¹ Supra-pubic cystotomy was performed and abdominal drainage established, the gluteal and operation wounds healing in the order named and the man recovering. In order to clear up the question of penetration by this curious route, Dr. Soulié performed a number of experiments on the dead body, which led to the following conclusions:—1. A cutting or pointed instrument passing through the buttock easily reaches the bladder, provided it enters through the smaller sacro-sciatic notch and is propelled in the direction of the anterior superior spine of the opposite side of the body. 2. The bladder is involved if the blade penetrates to a depth of from 28 to 75 millimetres (average 61 millimetres). 3. The bladder wound is almost invariably situated at the trigone, and nearly always close to the opening of one of the ureters. 4. The fact of the bladder being empty does not, in the above conditions, preclude its being wounded. 5. When the blade passes through the great sacro-sciatic notch the bladder is wounded towards the summit, but only if the viscus be full and if the knife is plunged to a depth exceeding 10 centimetres.

The Title of "Dr."

A friend of mine was some few months ago the guest of an American lady, the occasion being an evening party. He was astonished to find almost every other male guest being announced on his arrival as "Dr. So-and-so." On inquiry he discovered that these graduates were all American dentists. Now, although there exists in this country no law interdicting the assumption in society on the part of these foreign dental practitioners of any high-sounding title that may best please them, it would appear that they are not allowed to employ the prefix "Dr." in bills, circulars, or door-plates unless the degree has been granted by a French faculty. Two foreign dentists were recently prosecuted by the Syndicat des Dentistes de France for this offence. The defence was that as there was no illegal practice of dentistry the usurpation of the term "Dr." did not constitute an offence. The tribunal ruled, however, that the issuing of an advertisement or prospectus by a foreign dentist styling himself "Dr." who did not possess the degree of M.D. of a French faculty, was punishable. Had the dentist in question indicated in the incriminated advertisement the origin of his degree he would have escaped the fine inflicted of 100 fr. and the nominal damages of 1 fr. claimed by the prosecuting syndicate.

The New Maternity of the Beaujon Hospital.

On Tuesday last there was inaugurated the new maternity built in the gardens of the gloomy Hôpital Beaujon, situated in the Faubourg St. Honoré. The new building contains fifty-eight beds instead of the sixteen provided under the old order of things. The principal building (fifty-two beds) is exclusively reserved for accouchements. It comprises on the ground floor a consulting-room, on the first and second floors lying-in wards, on the third floor a convalescent ward, and finally on the fourth storey accommodation for the nurses and personnel generally. A separate block is reserved for suspicious and infected cases, whilst another block consists of a histological laboratory and a small museum. The entire cost of the building was 500 000 francs, or 8500 francs per bed. I take the opportunity of congratulating my friend Dr. Ribemont-Dessaignes (the physician-accoucheur of the Beaujon Hospital), to whose perseverance we owe this distinct progress.

Encysted Glandular Urethritis.

Hospital surgeons are but too cognisant of the rebellious nature of certain forms of urethritis in the woman. Dr. Verchère, surgeon to the St. Lazare Hospital for Venereal Diseases, informs us in the *Presse Médicale* of May 25th that he has solved the problem of the chronicity and intractability of the disorder in question by the discovery of its cause. He finds that the submucous tissue of the urethra contains in these cases a number of small cysts filled with thick brownish pus, some of these cysts being quite closed, whereas others communicate through a minute orifice with the urethral canal. These latter furnish the drop of pus seen in chronic urethrorrhoea to exude from the urethral orifice on pressure. But in the majority of cases there exist other cysts, which, being closed, no amount of pressure can evacuate. Their presence gradually determines a thickening of the areolar tissue in which they are situated, and

the urethra is felt as a thick cord when the finger is passed along the upper wall of the vagina. All intra-urethral treatment is useless in this disease, which Dr. Verchère has christened *urétrite glandulaire enkystée*. Despite its gonorrhoeal origin, the pus contained in the cysts is most frequently free from the gonococcus. Only one mode of treatment can bring about recovery, and that is a free incision of the lower wall of the urethra with complete removal of the cysts. One blade of a pair of scissors being introduced into the urethra and the other being in the vagina, an incision of the length of from one to one and a half centimetres is made. The lips of the incision being separated, ochre-yellow pouches the size of a millet seed or a pea are brought to view. Each of these cysts is dissected out, this being sometimes an easy matter. In the event of any difficulty being experienced, the urethral above and the vaginal mucous membrane below are respectively dissected from the areolar tissue, which latter is then, with its contained cysts, removed bodily. One or two sutures suffice to reconstitute the urethral canal, and the operation is at an end and recovery assured.

Vaccination in Italy.

THE care with which vaccination is practised in Italy is highly commendable, the lymph as a rule being scrupulously taken from calves inoculated with cow-pox. This wholesome innovation, however, is comparatively recent, and THE LANCET has had more than once to stigmatise the shameful frauds perpetrated on the Italian public, particularly of the southern and insular provinces, by the adulteration of the lymph supplied to the vaccinating stations. In Western Sicily, it will be remembered, there was a brisk trade in spurious lymph, one of the main ingredients in which was glycerine. The offenders were made an example of, and now all over the peninsula there are springing up "Istituti Vaccinogeni," directed by accomplished physicians, who make it their business not only to supply the purest lymph, but also to practise gratuitous vaccinations, at stated periods, to the poor. It is here, however, where the primary defect of the Italian prophylaxis against small-pox comes in. Compulsory vaccination in the sense in which it is enforced in Northern Europe, does not exist in Italy. The children of the well-to-do classes, the pupils at elementary schools, the recruits for the army and navy, the young candidates for offices under Government or in the municipal administrations, are all required *de rigueur* to be vaccinated; but still, to say nothing of the "submerged tenth," the seething proletariat that haunts such towns as Naples and Palermo, the "court-and-cellar" population of the great centres as a whole, there are families whose children are never vaccinated at all, to whom urgent appeals are addressed in the lay journals to repair on such and such a day to this or that "Istituto Vaccinogeno," to have their children brought under the protective operation. How often these appeals fall on deaf ears may, in fact, be read in the peculiarly solemn and even imploring language in which they are couched. The result of this partial enforcement of the prophylactic operation is all too conspicuous in the intermittent outbreaks of small-pox in the large towns and landward villages—places where the disease is always smouldering, ready to burst into flame whenever the specially favouring conditions are present. The new Parliament about to emerge from the throes of the general election going on to-day has many reforms to bring about, but none, I am sure, of more urgent necessity than the introduction into Italy of a vaccination system as thorough and all-reaching as that which has long shown such good results as, for example, in Denmark.

Rescue of the Drowning.

Our able professor of Medical Jurisprudence, Dr. David Toscani, presided the other day at a meeting of the "Società Romana di Soccorso agli Asfittici" (Roman Society of Aid to the Drowning)—an institution, I am sorry to say, which the increase of suicides in the Tiber makes yearly more necessary—and, as the result of its deliberations, it was resolved to announce a series of prizes for those who, at the risk of their own lives, shall, during the year now passing, have rescued

¹ Marseille Médical.

from drowning any individuals who, voluntarily or involuntarily, have been immersed in the river. Last year there were some brilliant deeds of heroism on the part of at least three Roman citizens in wresting unfortunates from a watery grave, affording fresh proof of the physiological fact embodied in the beautiful motto of your Humane Society, "Lateat scintillula forsan." Though not, perhaps, brought to the same perfection as in the stations on the Thames, the Serpentine, or on the Seine, the means of "salvataggio" available on the Tiber are much in advance of what they once were, and the interval between the rescue of the drowning man and the practice of artificial respiration, friction &c. is reduced to a minimum. In these precious moments so much depends on the promptitude and effect with which the operation and the special *matériel* of resuscitation are brought to bear on the semi-asphyxiated subject that no effort should be spared to perfect the discipline and enrich the apparatus of the "corps de sauvetage." Professor Toscani, with such assessors as Dr. Tullio Spaziani, Signor Ferdinando Gerardi, the engineer, and others interested in the humane work, professional and lay, may be trusted to place the Tiber service on a footing worthy of the Roman school, and with that conviction the public, to whose generosity they make appeal, will, I hope, unite in a response equally prompt and liberal.

Political Mania.

Excitement ran so high during the election that cases of mental disturbance amounting to mania have already been announced. One of these was at Rovigo, where, after a tremendous contest, the socialist candidate was defeated, and one of his most fervid committee-men who had wrought himself to an extreme state of tension felt the disappointment so keenly that inhibitory paresis declared itself in a number of violent excesses. He had, in fact, to be removed to the Manicomio at Rovigo, where his shrieks and struggles became so alarming that he was put into a *camicia di forza* (strait-waistcoat). Other victims to mania from the same cause—some of them homicidal in their outbreak—are reported from the Southern provinces. Hitherto Italians have taken their political elections with a sober self-possession which outsiders are apt to call indifference, but the agitation, directed against Crispi and availing itself of the most violent weapons of party warfare, has acted on them like a pernicious stimulant and driven them to words and deeds so extravagant as in many instances to pass the bounds of sanity. The same cause nexus between political excitement and mania has been observed and commented on in France, where the eminent *aliéniste*, M. Regnard, precisely nine years ago published a monograph on its various forms. One of these he classified as "monomanie grandiose," a not unfrequent result in the amateur saviour of society; and he described a typical example of it in a young ecclesiastic who, after making himself a public nuisance by posing as a self-styled "complementary supplement to Leo XIII.," had to be placed in the Maison de Santé. Last year in the House of Commons the increase of lunacy in Ireland was, in a discussion on the Commissioners' report, attributed by more than one member to the high-pressure excitement of the last political decade; and certainly the "Italian Ireland," as Sicily has been not inaptly called, has within the twelvemonth been prolific of agitation and moral tension which the Southern brain is little able to bear up against. "Mania contionabunda" has already found its way into alienist classification south of the Alps, where the "Morbus Comitialis" has also become all too common, though in a sense somewhat different from that of Celsus. The whole phenomenon of political mania has, indeed, been so pronounced in Italy ever since Signor Crispi's Cromwellian closure of the Camera dei Deputati that we may expect it to form the subject of one of those interesting studies in which no one has more distinguished himself than Professor Lombroso.

Coming Congresses.

Besides the Congress on International Medicine, at which the question of sero-therapeutics will have a "full-dress debate" all to itself, there will be held in Rome, also in September next, a great Geographical Congress, the second of the series which was initiated three years ago in Genoa on occasion of the quatercentenary of Christopher Columbus. Elaborate arrangements are already in progress for the reception and entertainment of foreign delegates, who will receive all information on applying to

the secretary of the Congress, at the rooms of the Società Geografica Italiana, Via del Plebiscito, Rome. Climatology will form an interesting feature of the *agenda*, and the experience of more than one medical explorer as to the resources of the dark Continent in health-resorts—notably, the Asmara uplands of Abyssinia—will be available in its discussion. I may add, as an item of news, that the place of Padre Denza at the Specola Vaticana has just been filled by the appointment of the Padre Bertelli, the distinguished physicist and seismologist. The Padre Denza¹ could have no abler successor than the Padre Bertelli, whose investigations of air-currents and telluric storms will occupy a prominent place in the history of climatology.

June 2nd.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Ménière's Disease.

At the last meeting of the Vienna Medical Club Dr. Frankl read a paper on Ménière's Disease. That observer was the first to show that persons might be seized with sudden deafness, vertigo, tinnitus aurium, and vomiting. This deafness may be complicated with facial paralysis. Cases not uncommonly occur where hearing is lost in consequence of injury, and post-mortem examination shows that a fissure of the occipital bone passes through the labyrinth and extends to the inner surface of the tympanic cavity. Ménière's symptoms, however, may result from syphilitic diseases of the labyrinth, and some poisons—such as quinine, nicotine, and nitrate of silver—may produce similar effects. Vertigo and tinnitus are the most important symptoms. Some patients suffer from continual vertigo, which ceases only in a constant position of the body (lateral or the head downwards); this is the so-called status Ménièreus. Such patients show plunging movements as if they would fall sideways, and this condition characterises Ménière's disease, for neurasthenia presents no plunging movements. Moreover, the oscillatory, rotatory, or deviating movements of the eyes are of great importance. These paroxysms are accompanied by ataxia and increased reflexes. Dr. Frankl exhibited a patient twenty-nine years old who was admitted to hospital some eight months ago. His illness began with congestion in the head and weakness. After having recovered his senses he experienced vertigo and tinnitus and vomited a slimy substance. Since that time he has suffered from imperfect hearing in the right ear and is harassed by a noise which he compares to that of boiling water. Dr. Frankl explained that this condition may be regarded as a consequence of a disease of the semicircular canals caused by hæmorrhage into the labyrinth.

Treatment of Spasmodic Torticollis.

Dr. Heinrich Weiss has published² a case of Spasmodic Torticollis treated by Curare. Following Professor Benedikt, he describes five forms of torticollis: (1) those which occur continually or in paroxysms; (2) clonic and tonic forms; (3) unilateral or bi-lateral spastic forms; (4) cases where several muscles are affected; and (5) torticollis with muscular hypertrophy. All these cases apparently occur on both sides. The muscles of the side which seems to be sound become atrophic, whereas those of the affected side show hypertrophy. The symptoms being misinterpreted, it has been proposed to treat the apparently sound side by faradisation, and the success obtained was trifling. Inveterate cases are to be treated by nerve stretching. At a meeting of the Vienna Medical Society Dr. Weiss exhibited a patient who suffered a short time ago from torticollis with spasms of the right sterno-mastoid muscle, the rotators of the head and vertebral column. The head was turned round the vertical axis with the chin to the left and round the sagittal axis to the right, the occiput almost touching the right shoulder; the right sterno-mastoid was hypertrophied. As arsenic, bromine, and faradisation of the left side had been used without any success, nerve stretching was performed. The right accessory nerve, which was stretched, was found to present a peculiar condition—that of hyperlymphosis nodosa. A too forcible operation being hazardous, only the bundle of fibres at the place of entrance into the muscle was

¹ Vide THE LANCET, Dec. 22nd, 1894.

² Therapeutische Wochenschrift.

stretched. Three weeks after this operation the previous symptoms returned, and Dr. Weiss injected a solution of curare (half a Pravaz's syringeful) into the neck. The solution contained 0.15 gramme (=2.5 grains) curare and 10 grammes water (=167 grains). The injection was made every two days; the patient's condition improved from day to day, and at present he is entirely free from torticollis. As for the strength of the preparation, the solution is to be straw-coloured. At first half a syringeful is to be injected, and the amount is to be increased until tremulousness is induced.

The Use of Trional for the Sleeplessness of Children.

Dr. Klaus³ has used trional in some diseases of children, such as chorea, epilepsy with persistent sleeplessness, and sleeplessness due to indigestion. He has obtained gratifying results, but in one case symptoms of irritation were observed. According to the age he recommends the following doses: one month to one year, 0.2 to 0.4 gramme (3 to 6 grains); one to two years, 0.4 to 0.8 gramme (6 to 13 grains); two to six years, 0.8 to 1.2 gramme (13 to 18½ grains); six to ten years, 1.2 to 1.5 gramme (18½ to 23 grains). The remedy is to be taken in hot milk or honey half an hour after the evening meal.

Inebriates in Lunatic Asylums.

A paper on this subject was recently read by Dr. Tilowsky, Director of the Lower Austrian Lunatic Asylum at Ybbs. He said that inebriates could not be reclaimed in lunatic asylums, alcohol being prescribed there for dietetic or therapeutic reasons. Experience, however, has proved that recovery from drunkenness was possible only by complete abstinence from alcohol. Temperance does not help, for the taking of a small quantity of liquor causes an inordinate thirst for more. Dr. Tilowsky therefore advocates the absolute exclusion of drunkards from lunatic asylums and the institution of compulsory measures, such as already exist in the English colonies and the United States. If it is requisite in the interests of public health to isolate patients affected with typhus fever or trachoma, it is also a duty of society to protect lunatics from association with inveterate drunkards and to found inebriate asylums, for drunkards in their lucid intervals are disturbing elements in lunatic asylums by reason of their mental superiority.

A Peculiar Case of Suicide.

Dr. Aczel has published in the Hungarian medical journal *Gyógyászat* the following case of suicide. Being recently sent for he found a woman bathed in blood and beside her splinters of glass and a bloody knife. In her throat there was an incised wound six inches long and her larynx was removed, but the carotid arteries were unhurt and pulsated on both sides. She was still alive, but her breathing was deep and irregular. The larynx was found in the blood. The woman was admitted to hospital and died in six hours. It is singular that such terrible injuries had not caused instantaneous death.

Dr. Heitzmann.

The eminent abilities of the well-known author of the "Anatomical Atlas" not being at first recognised at Vienna, he left his native town some twenty years ago and founded a microscopical institution at New York. Last Friday he was the guest of the Vienna Medical Society, and read a paper on his microscopical researches. He was the first to prove that the red blood-corpuscles possess a reticular structure. When treated with chromate of potash they show amoeboid movements, and half an hour later filaments reticularly interwoven pass through the inside of the corpuscles, the hæmoglobin being enclosed in this network. This reticulum may also be found when blood is mingled with stale urine. The red blood-corpuscles, therefore, possess life as protoplasm, the reticulum exactly representing the living matter. Where much living matter is found the constitution of the individual is good. Dr. Heitzmann infers the nature of the constitution from the quality of the reticulum, and has been able to predict the end of an illness three weeks in advance by means of microscopical examination. The organism is a living continuous structure and not an aggregation of individual cells.

June 2nd.

³ Kijinsche Rundschau.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Opposed to Vivisection.

A SURGEON of Philadelphia recently proposed to splice a divided nerve with a section of a dog's nerve, and applied to the keeper of the public pound for the animal. The vagrant dogs were in the keeping of the Society for the Prevention of Cruelty to Animals, and the request was promptly refused by a lady member. "In reply to your note," she said, "I will say that, although I should always approve of sacrificing a dog's life to save that of a man unless the latter was a curse to the world and the former a boon and blessing (which is sometimes the case), I think that I am justified in refusing to give you one of the dogs at our pound for the experiment, which may prove of benefit to one of your patients or may not, the latter being the most likely alternative." The surgeon replied: "Aside from myself, there are three parties who are to be considered in this matter: first, the dog; second, the man; and third, mankind. First, the dog. I stated to you that the dog would not suffer, that he would be treated with the same care as the man, and that after the operation I should continue the anæsthetic till the dog was dead. Secondly, the man. This man knows what I am going to do and is anxious to have it done. His leg is paralysed. If by an ordinary surgical procedure I can re-establish the continuity of the nerve I may be able to cure his paralysis. In that case I should not have recourse to the dog. If, on the contrary, the gap between the two ends of the nerve is so great that I cannot bring them together, either the man must be condemned to paralysis for life or some other means must be tried to re-establish the nerve and so restore to him the use of the leg. This might be done by the process of nerve grafting. Yet you refuse me a dog on the ground that it is an experiment. Granting that it is, it is at the most a perfectly harmless experiment, for it would not be more painful than any ordinary operation; and even if it absolutely fails, it leaves the patient not a whit the worse off. If it succeeds, it will be of the greatest possible service to him. Thirdly, mankind. The only way in which surgery can make any progress is by testing new methods of treatment which have at least a reasonable prospect of success. In your misguided zeal for dogs you are guilty, in my opinion, of cruelty to this man, and cruelty to all mankind, because you thwart scientific progress under the guise of love for animals. You would condemn to the torture and disabilities of accident and disease people who have happily been rescued by the more humane scientists of my profession."

Practical Test of the Qualifications of Trained Nurses.

The hospitals of New York have each a training-school for nurses. It has been customary to have public graduating exercises when the diplomas have been conferred. The Presbyterian Hospital made an interesting departure a few days ago by giving a demonstration of the methods of work by nurses, and of their ability to perform their tasks. Patients were brought from the wards and laid on cots and operating-tables. Then the more difficult and delicate work required of the nurses was practically shown. First came an object-lesson on the making of beds and the changing of sheets and mattresses without removing the patient from the cot, and then the lifting of the patient from one cot to another, all being done quickly and with no disturbance of the subject. After this followed the application of the different kinds of bandages to the head, chest, abdomen, arm, leg, hand, and foot, one of the bandages, forming a kind of jacket, encasing the subject from the neck to the hips. Hot and cold water applications were made, and the method of dry-cupping as practised was practically shown. The method of artificial respiration, used when the patient's breathing is deficient or has stopped, consisting of raising and lowering the arms, was likewise exhibited. One of the most interesting treatments given by the nurses was the cold bath to reduce the temperature in cases of typhoid fever. The subject was lowered into a bath of cold water, accurately regulated, and kept there for several minutes, being vigorously rubbed by the nurses all the time. The making and filling of icebags and the preparation of poultices were performed rapidly. One subject supposed to be suffering from a disease of the throat

had her throat sprayed and was then enclosed in a sheeted framework, where a preparation was administered by means of a vapour.

Obituary.

JOHN ANTHONY, M.D. CANTAB., F.R.C.P. LOND.

ON June 1st, at Birmingham, Dr. Anthony passed peacefully away at the ripe age of 81 years. In many respects Dr. Anthony was a remarkable man, his life being devoted to the pursuits of natural and applied science. At an early age he became a Scholar of Caius College, Cambridge, and a Mickleburgh scholar in chemistry. He took his M.D. degree in 1859, and was made a Fellow of the Royal College of Physicians in 1876. His younger brother was Mark Anthony, the celebrated painter of landscapes. Dr. Anthony was also a devoted lover of nature in every shape and form. He had travelled extensively, and made abundant use of his exceptional powers of observation and his intelligence. An accurate and enthusiastic worker in scientific research, particularly in astronomy and microscopical investigation, he acquired all the latest and modern appliances relating to these subjects. With a wide range of knowledge and a disinterested and impartial mind he enjoyed his life in the midst of his pursuits with singular felicity and ardour, seeing that by reason of his love of work and admiration of all nature's wonders he passed his time unmoved by worldly perturbations. Some forty years ago he was physician to the General Dispensary and to the Children's Hospital, but never took an active part in practice. His studies engaged the whole of his time, and his collections of natural history and scientific apparatus occupied his mind and his time. Genial, kind-hearted, and full of the most varied information, his place will be hard to fill for those who knew him well and partook of his friendship and his memories.

CHARLES JAMES SYMONDS, M.R.C.S. ENG., L.R.C.P. ED.

THE death occurred on May 21st, at Mutley House, Southampton, of Mr. Charles James Symonds, M.R.C.S. Eng., L.R.C.P. Edin., at the age of seventy-six years. Deceased was the son of the Rev. Samuel Symonds, M.A., Rector of Philligh, Cornwall, and a Justice of the Peace for that county. He was educated at Guernsey College and St. Bartholomew's Hospital, London. After taking his qualifications he joined the Royal Mail Steamship Company, and was surgeon to the troops conveyed by them to and from the Crimea, he being present at the Siege of Sebastopol and the Battle of the Alma. After his marriage, in 1859, Mr. Symonds gave up the sea, and in 1867 he commenced practice at Woolstone, near Southampton, where he remained for a lengthened period, and as a medical practitioner was known for miles round. He was held in the highest respect and esteem by all who knew him, and among the poor—to whom he was always most generous and kind—his name was quite a household word. He lived to a good old age, and although now numbered among the great majority his memory will ever remain green with those whose pleasure it was to be acquainted with him.

ROBERT HODGENS LLOYD, M.D. BRUX., M.R.C.S. ENG., L.S.A.

DR. LLOYD, whose death occurred on May 10th, had for nearly twenty years held the responsible position of medical superintendent of the Lambeth Infirmary, and was highly esteemed among his colleagues in the metropolitan Poor-law medical service. He studied medicine at Westminster Hospital and took the diplomas of the Royal College of Surgeons of England and the Society of Apothecaries in 1869. Under the auspices of the National Society for the Aid of the Sick and Wounded he served in the Franco-German campaign of 1870-71, and soon after his return to England he was selected to be medical superintendent of the Woolwich Union Infirmary. In 1876 he succeeded the late Dr. Bullen as medical superintendent of the Lambeth Infirmary, and held the appointment up to the time of his death, which occurred at the comparatively early age of forty-seven years. Dr. Lloyd contributed papers to THE LANCET on various subjects during a series of years.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

LAST week we gave a detailed report of the proceedings of the Council on Tuesday, May 28th, and Wednesday, the 29th. On Thursday, the 30th, and Friday, the 31st, the whole time of the Council was taken up with the consideration of a single item of business—namely, the case of Mr. Robert Fitzroy Benham, registered as Member of the Royal College of Surgeons of England 1881. Mr. Benham had been summoned to answer a series of charges in relation to the Queen's Jubilee Hospital, Richmond-road, Earl's-court, Kensington, formulated by the solicitor of the Council on the complaint of the Medical Defence Union. He appeared before the Council, attended by counsel and solicitor, and offered an absolute denial to each of the charges made against him. Several witnesses were examined on either side and a great number of documents were read, and the Council, at the close of the second day, after deliberating in private for a considerable time, announced to Mr. Benham that they found him not guilty of the charges laid against him. When the minutes of the proceedings came to be read on the following day the President informed the Council that the trial had been an additional cost to the Council of nearly £600.

The position of the Council towards penal cases is one the profession will wish to see defined, if not strengthened. It does not, of course, follow that the time and money of the Council are thrown away in investigating charges against a practitioner which end in nothing but his acquittal. On the contrary, no disciplinary body could be better engaged. But it is necessary that a tribunal should have proper power to try or its seriousness of import will be jeopardised. In the case of Mr. Benham it almost appeared as if the defendant desired the investigation by the Council of the charges brought against him, and it will be a curious use of the Council's investigations that they should be courted by a medical man to clear his character of charges which he should meet in a court of law.

In one case the course of events was curious. The Medical Defence Union withdrew the charges it had made. Dr. Bateman explained that he did so in consequence of the witnesses who had signed the statements on which he relied afterwards signing other statements contradicting these. The Medical Defence Union has not had an easy time of it. It is open to abuse from all sides, and it came in for not a little in connexion with this case. It has a difficult part to play, and when its able representative has to contend with such a foeman as Mr. Bucknill, Q.C., the contest is scarcely a fair one. It would seem but fair to Dr. Bateman that the Union should employ counsel in those cases which it brings before the Council. But even so the collapse which happened in this case could not have been averted. The honorary secretary explained that the Union had been at an expense of £60 with no result and with no credit to itself, while the abortive action told heavily upon the funds of the Council. The profession is under a great debt to the Union for the work it has done, and it will be a pity that it should not make that work more effective and complete. The General Medical Council is less to be pitied. It has its highly paid lawyers, and it is not too much to expect that they should facilitate the trial of fit cases and save the Council from listening to those which cannot be satisfactorily dealt with under its powers.

Up to Wednesday it is not too much to say that the most striking feature of the present meeting was the attempt of Sir Walter Foster to change the whole spirit and action of the Council towards the midwives question. There had been premonitory intimations that Sir Walter Foster was about to make what Dr. Donald MacAlister called "this sharp turn." But, to do Sir Walter Foster justice, he made it with no sense of embarrassment. He proposed to abolish the word "midwife," in spite of Genesis and the language and custom of law and the common people, for the term "midwifery nurse." This was rejected by the Council, as was a compromise suggested by Dr. Glover—the use of the term "nurse-midwife." Sir Walter Foster made no secret of his objection to legislation of this sort in any form. His action was the more remarkable, as he had himself moved a resolution in 1889 urging the Government to bring in such a Bill, alleging that much suffering and mortality were going on among poor women for want of it. "He was no pedant" and not hindered at all by such an inconsistency. The consistency of the Council was, of course, not more to be revered than his own, and he spoke as if he were quite prepared to disregard the action of the Council for twenty years. On Tuesday of this week he excelled himself in proposing that instead of "woman" the word "person" should be used. The effect of this would be to enable men to be registered as women after a few months' training. In other words, it would be an invitation to the unqualified assistants to take the midwifery practice into their own hands. The Council became properly alarmed at this proposal, some of Sir Walter Foster's Scotch and Irish supporters (the Bill, by the way, not affecting either Scotland or Ireland) even hesitating and holding back. Fortunately, the proposal was rejected by 21 votes to 7, and thus a real danger to the profession was averted.

On Wednesday afternoon, on the proposal of Sir William Turner that the amendments of the Bill made by the Council in committee should be adopted and forwarded to the Government as a reply to its wish for the opinion of the Council, Sir Walter Foster proposed a motion practically rejecting the Bill or any other legislation to the same effect. But the Council rejected his proposal by eighteen to seven, and carried that of Sir William Turner, the original motion, by twenty-three to six. His discomfiture would have been still more complete, but for the support of a few Scotch and Irish members, though, as we have said, the Bill did not apply to their divisions of the country. Sir Walter Foster's opponents had an easy task in showing how the credit of the Council as a deliberative and advising body was at stake in the matter. Dr. MacAlister spoke with great force, and Dr. Glover pointed out that the Bill was the most modest of proposals for meeting a great evil and that the alternative remedies were likely to be disastrous to the profession.

Dr. Tirard has been invited and has consented to act as secretary to the Pharmacopœia Committee and to render assistance to the President in matters relating to the preparation of the new edition of the Pharmacopœia. We congratulate the Council and Sir Richard Quain upon having secured a gentleman so eminently competent to discharge the requisite services. Dr. Tirard is Professor of Materia Medica and Therapeutics in King's College, London, and the author of "The Prescriber's Pharmacopœia," and has been an examiner in materia medica at the University of London, at the Royal College of Physicians of London, and to the Conjoint Board; so that to the result of his ten years' work at King's College there must be added the amount of varied and practical experience that comes

from exercising the arduous task of examining, placing him in an excellent position to know the directions in which the current edition of the British Pharmacopœia is useful to students and practitioners and in which it falls. As physician to King's College Hospital and the Evelina Hospital for Sick Children, Dr. Tirard also will be able to lend the assistance to the committee of the practical physician, as well as that of the skilled pharmacologist, so that from every point of view we are pleased to be able to notify his appointment.

SATURDAY, JUNE 1ST.

The Council resumed to-day with Sir Richard Quain again in the chair. The practitioner concerned in the first disciplinary case on the agenda did not appear when called upon, and Mr. Muir Mackenzie informing the Council that the registered letter containing the summons had been returned, it was decided to postpone the consideration of the case until the November session.

The Case of Mr. George Francis McCarthy.

The Council then proceeded to the case of Mr. George Francis McCarthy, registered as Lic., Lic. Midwif., 1876, K. Q. Coll. Phys., Irel.; Mem. R. Coll. Surg. Eng., 1876, who, on the complaint of Mr. Braxton Hicks, coroner, had been summoned to answer the following charge:—

"That he systematically acted as cover to an unqualified person named Francis Morley Coppin, and by acting as cover to him, and by allowing him to use his (McCarthy's) name and qualifications, and by his presence and assistance, enabled the said Francis Morley Coppin to practise and attend patients as if he were a duly qualified registered practitioner."

Dr. BRAXTON HICKS addressed the Council in support of the charge. He explained certain circumstances brought to light at the inquest on the body of a man named Collet, who died in Oakley-street, Lambeth, in the course of last February. These went to show that Coppin was in the habit of attending serious cases and treating them on his own responsibility, the people understanding him to be "Dr. McCarthy" and a duly qualified practitioner. He also presented to the Council the death certificate, bearing Mr. McCarthy's name, of a child which died when Mr. McCarthy was away at Brighton on holiday. Mr. McCarthy, said Dr. Braxton Hicks, saw the child last on Feb. 13th, and it died on the 18th, and in the presence of two witnesses Coppin filled up the certificate. He produced two other death certificates which he claimed were in Coppin's handwriting.

Cross-examined by Mr. Schultess-Young, who appeared for Mr. McCarthy, Dr. Braxton Hicks said he did not suggest that Coppin shared with Mr. McCarthy the earnings of the practice; all he suggested was that Mr. McCarthy must have known that Coppin was acting as a qualified practitioner. Coppin was not a man learning the profession; he was what might be called a stock unqualified assistant.

Mr. McCarthy afterwards was examined. He stated that he came to London in 1876, and for a year acted as assistant to Coppin's father. He left for a time, but returned and purchased a partnership with Dr. Coppin senior. That partnership continued until 1881, when he acquired the entire practice. Mr. Coppin, jun., had acted as his assistant from time to time, according to the exigencies of the practice, but he had no responsibility for the practice. Since the certificates mentioned came to his knowledge he had dispensed with the services of Coppin, and he was carrying on the practice without an assistant. He gave Coppin no authority to sign death certificates for him.

Mr. EDWARD JOHN SMITH, registered practitioner, residing in Lambeth-walk, gave evidence as to his habit of acting for Mr. McCarthy while the latter was away from home.

The PRESIDENT, announcing the decision of the Council, said it was his duty to tell Mr. McCarthy that they were of opinion that he committed the offence charged against him, but at the same time, moved with merciful consideration, they postponed proceeding further in the matter. The Council determined that he should be called up again in November in order that he might produce evidence as to the manner in which he was conducting his professional duties.

The Case of Mr. Samuel Frederick Murphy.

The PRESIDENT suggested that the Council should dispose of the next case on the programme of business, that of

Mr. Samuel Frederick Murphy (registered as Licentiate of the Royal College of Surgeons in Ireland, 1885), who had been summoned to appear before the Council to answer a charge of covering an unqualified person at Coventry. He said he was informed by their legal adviser that the case might be dealt with in two or three minutes.

Dr. McVAIL objected to their legal adviser assuming anything of the sort.

Mr. WHEELHOUSE moved the suspension of the Standing Orders for such time as the Council saw fit.

Only Dr. McVail voted against this proposal.

The PRESIDENT pointed out that it would save expense to the parties and the Council if the case could now be taken.

The parties were called, and Dr. Bateman appeared for the Medical Defence Union in support of the complaint. Mr. Murphy did not appear.

Mr. MUIR MACKENZIE said that Mr. Murphy's case was one of covering a notorious person called Millerchip, and it was brought on the complaint of the Medical Defence Union. There was very full evidence of Mr. Murphy's having covered Millerchip and permitted him to sign his certificates. Through his solicitor Mr. Murphy put in a defence, in which it was stated that on the complaint being made known to him he had at once severed his connexion with Millerchip, that he did not think what he was doing would be looked upon so seriously, that he desired to apologise in the simplest manner possible, and that if the Council overlooked the offence he would take care not to offend again. The solicitor who wrote added that Mr. Murphy was a young man, and he trusted the Council would accept his apology and not inflict upon him the penalty of removal from the Medical Register. He (Mr. Muir Mackenzie) suggested that the Council should accept the apology offered. They could record in their minutes that as Mr. Murphy had apologised for the offence, stating that it was committed through inadvertence, the Council did not see need to proceed. That would not prevent Mr. Murphy's being summoned on a fresh charge.

Dr. HERON WATSON asked whether Mr. Murphy should not have appeared. It was the least thing he could have done in order to show that he respected the Council.

Dr. FRASER pointed out that Mr. Murphy had pleaded guilty to doing what the Council had punished other men for doing, and it would be a rather unreasonable way of dealing with the case to adopt the course suggested.

Dr. HECTOR CAMERON said that Mr. Murphy had been enabling a man to practise against whom there was a long list of convictions. He must have known that this man Millerchip had been taken off the Register. He had been summoned and he ought to have appeared.

Dr. CHURCH said that he pleaded youth also.

Mr. CARTER said that in the documents in the case they had a letter of March 29th and another letter in reply to it.

Dr. McVAIL moved that consideration of the case be postponed till Monday, and that Mr. Murphy be summoned to attend on that day.

Sir WM. TURNER submitted that Mr. Murphy must make an appearance. He did not see why the Council should allow anyone to treat them in the way Mr. Murphy was doing. He seconded the motion.

Dr. ATTHILL objected to postponement. This gentleman had pleaded guilty, and in his opinion the Council should adopt the same course as was taken in the case of Mr. McCarthy. They should accept the apology, postpone punishment, and call upon Mr. Murphy to give evidence in November that in the interval he had conducted his practice in a regular manner.

The PRESIDENT thought there were strong reasons for the case going on.

Dr. FRASER said it seemed possible that, if the man came up on Monday, he might give some reason to enable the Council to take a favourable view of his case. But in the meantime he had pleaded guilty, and unless he could give some reason why the Council should not proceed further, his name should be removed from the Register.

Dr. HAUGHTON suggested that there was nothing to prevent Mr. Murphy's being summoned to appear on Monday. It was treating the Council with rather scant courtesy, and was rather an off-hand way of proceeding to write, "I plead guilty; let me off."

The motion was then put and was unanimously carried.

The Council adjourned at ten minutes past four o'clock.

MONDAY, JUNE 3RD.

The Council met again to-day, Sir RICHARD QUAIN in the chair.

The Case of Mr. Samuel Frederick Murphy.

The Council took up the case of Mr. Samuel Frederick Murphy, who was summoned to appear on the following charge as formulated by the Council's solicitor: "That he had acted and did act as cover to an unqualified person named Thomas Millerchip, who resided and carried on a medical practice at 4, Swanswell-place, Coventry, and by his presence and the aid of his name and professional qualifications enabled the said unqualified person to carry on, and assisted him in carrying on, a medical practice as if he were duly qualified."

Mr. Murphy did not appear.

Mr. MUIR MACKENZIE said that on Saturday afternoon a telegram had been sent to Mr. Murphy at 4, Swanswell-place, Coventry, advising him that his case had been postponed till Monday at 2 o'clock, and that his attendance was imperative. As Mr. Murphy did not now attend, the Council, Mr. Muir Mackenzie added, could adjudicate on his case.

Dr. BATEMAN then, for the Medical Defence Union, put in three certificates of Millerchip's convictions in criminal courts, and said he was a person whose case had given a good deal of trouble in Coventry, four or five medical practitioners in the district having been brought before the Council on a charge similar to that now made against Mr. Murphy. He read affidavits in support of the charge.

Mr. MUIR MACKENZIE again read the defence sent to the Council on behalf of Mr. Murphy.

After a brief conversation, in the course of which it was elicited that Mr. Murphy had not attended at the offices in Oxford-street at all, the Council considered the case in private. When, five minutes or so afterwards, the public were readmitted,

The PRESIDENT said the Council had decided that Mr. Murphy had committed the offence charged against him, that the offence was in the opinion of the Council infamous conduct in a professional respect, and that the Registrar should be directed to remove Mr. Murphy's name from the Medical Register.

A Case Withdrawn.

The next business on the programme was the case of a gentleman who had been summoned to answer a charge of covering an unqualified person. On the charge being read by Mr. Miller, the Registrar,

Dr. BATEMAN asked to be allowed to make a statement in regard to the case.

Mr. MUIR MACKENZIE: You wish to withdraw it?

Dr. BATEMAN gave his reasons for withdrawing. The Union had made the usual inquiries at a considerable cost, and finally received from their agent statutory declarations which were drafted by their legal advisers and signed by certain persons. The evidence thus collected was forwarded to the General Medical Council in the usual manner, and upon it a summons was issued; but to his (Dr. Bateman's) surprise and utter astonishment, when the defence was issued it contained statements from the original set of witnesses entirely contradicting their former evidence. As the truth could only come out under cross-examination, and as they had no power to compel the attendance of these persons, he felt that it would be hopeless to attempt to arrive at or do justice to anyone connected with the case, and after some further conversation the Council deliberated for a few minutes in private. On the public being readmitted the President announced that the following was the decision at which the Council had arrived: "Dr. Bateman having declined to proceed further with his complaint, on which the summons was issued, the Council does not think fit to proceed further with the case at this session."

The Apothecaries' Hall of Ireland.

The next business on the notice paper was the following motion in the name of Dr. Atthill—viz.: "That the Council consider the application of the Apothecaries' Hall of Ireland for the appointment of examiners in surgery, without waiting for the report of the Examination Committee on the autumn report on the Conjoint Examinations of the Royal College of Surgeons and Apothecaries' Hall of Ireland."

Sir PHILIP SMYLY moved that this motion be not put. He thought it premature to discuss this question before they had before them the report of the Examination Committee.

Dr. ATTHILL reminded the Council that they were near

the end of the session, and if they did not deal with this question now it would probably have to be postponed till November.

Dr. CHARLES MOORE thought the report should come first. The motion was not seconded, and the Council accordingly passed to the next business.

Removals from the Register.

Dr. BATTY TUKE asked the President whether, in pursuance of the resolution adopted by the Council on the recommendation of the Executive Committee, the solicitor had taken any proceedings against persons assuming qualifications of which they had been deprived by the licensing authorities, and whose names had been erased by the Council from the Medical Register.

The Council considered this question in private, and when the public were readmitted the President merely announced that he had answered it.

Medical Practice in the Netherlands.

Dr. BATTY TUKE moved: "That, in accordance with the recommendation of the Education Committee, the President be requested to inform the Lord President of Her Majesty's Privy Council that the General Medical Council, while they fully appreciate the importance of the privileges granted to British medical practitioners by the provisions of the Royal Decree of March 26th, 1895, transmitted by the Dutch Minister of Foreign Affairs, are of opinion that these do not constitute such 'privileges of practising' as are contemplated in Section 17 (1) of the Medical Act (1886), and accordingly do not deem it expedient that the Netherlands should at present be recognised by Her Majesty's Government as a foreign country to which the provisions of this section should be applied." The section of the Act referred to was as follows: "Her Majesty may from time to time, by Order in Council, declare that this part of this Act shall be deemed on and after a day to be named in such Order to apply to any British possession or foreign country which in the opinion of Her Majesty affords to the registered medical practitioners of the United Kingdom such privileges of practising in the said British possession or foreign country as to Her Majesty may seem just; and from and after the day named in such Order in Council such British possession or foreign country shall be deemed to be a British possession or foreign country to which this Act applies within the meaning of this part thereof; but until such Order in Council has been made in respect of any British possession or foreign country this part of this Act shall not be deemed to apply to any such possession or country; and the expression 'the prescribed day' as used in this part of this Act means, as respects any British possession or foreign country, the day on and after which this part of this Act is declared by Order in Council to apply to such British possession or foreign country." This section contemplated the case of a foreign country which afforded to the registered medical practitioners of the United Kingdom "privileges of practising" in the said foreign country. It did not appear to the Education Committee that such privileges were as yet afforded by the new decree of the Netherlands. A British practitioner was, they understood, to be permitted to practise in the Netherlands only on condition that he passed the "theoretical medical examination" of that country, and so obtained a Dutch qualification.

Dr. MACALISTER, in seconding the motion, said he was delighted to recognise in the concession of the Netherlands the first fruits of the admirable memorandum drawn up by the President and approved by the Council and forwarded to foreign nations. In this particular case, however, Holland asked for a privilege which at present was only conceded to India and some of our Australian colonies who put the licences of British medical men on the same footing as their own. In the case of Holland they insisted upon a Dutch examination, which made the case a little different. They must acknowledge a great step forward, but at the same time the committee thought that the reciprocity was as yet somewhat one-sided.

The motion was adopted, and on the suggestion of Sir WILLIAM TURNER it was agreed to send also to the Lord President some portion of the report of the Education Committee on the subject.

The Case of Mr. John Eustace Dennan.

On the recommendation of the Dental Committee the Council decided to remove from the Dentists' Register the name of Mr. John Eustace Dennan, who on Jan. 7th, 1895,

at the Central Criminal Court was convicted of obtaining money by false pretences and sentenced to ten years' penal servitude. Mr. MUIR MACKENZIE said that Mr. Dennan had written a long memorial complaining that his trial was an unfair one.

The Cost of the Disciplinary Cases.

The PRESIDENT said the Council would be glad to find they had got to the end of the disciplinary cases. The expense of these cases to the Council had been £700. Of course it was their duty to deal with these cases, but the question was whether the present preposterous system could not be modified in some way. It had been suggested that all the penal cases should be postponed till the end of the other business, and taken then by the members who were able to remain. In this way the expenses might be reduced.

Midwives Registration Bill.

The Council then went into committee to consider the Midwives Registration Bill and the report by the committee upon it.

Sir WILLIAM TURNER presented the report.

This document set forth that the Bill had been transmitted by the Lord President of the Privy Council to this Council with a request that the Council would favour him with any observations they might desire to offer on it. It was introduced into the House of Lords by Lord Balfour of Burleigh, and had passed the second reading. The Bill proposed that the term "midwife" should mean "a woman who undertakes to attend cases of natural labour without the direct supervision of a medical practitioner"; that a register of midwives should be kept in pursuance of the Act; and that a "Midwives Board" be constituted under the Act for the purpose of carrying out its provisions subject to the approval of the General Medical Council. The report then gave the various resolutions on the subject passed by the Council. Summarising these, it said that since 1877 the Council had on more than one occasion expressed the opinion that it would be desirable to provide by legislation for giving certificates to competent midwives; that the lives of women in labour should, as far as practicable, be protected from the incompetent; and that, whilst the Council did not approve of the institution of a central register for midwives, it was of opinion that there should be local registers, under the charge of the local governing authorities; that the Council would be willing to advise as to general rules of education, examination, and discipline, but would not undertake any duties of detail as to the registration of midwives or as to the local arrangements for licensing and controlling them. The committee recommended that the Bill be amended as follows:—

"That the word 'midwives' should be struck out of the title of the Bill and out of the several clauses, and that the term 'midwifery nurses' be substituted for it. N.B.—This amendment was carried on a division by a majority.

"Clause 2.—That in lines 9 and 10 the words following 'natural labour' should be struck out, and that the words 'but not to discharge any other duties than those of a midwifery nurse' should follow the words 'natural labour'.

"Clause 3, subclause 2.—That in line 23 the word 'registered' be substituted for 'legally qualified'.

"Clause 4, line 19.—After 'surgery' add 'or midwifery, except as defined in this Act'; line 20, add 'if any such name, title, or designation is assumed, or if any certificate of death or of stillbirth be granted, the midwifery nurse, on conviction, should be subjected to a fine not exceeding'

"Clause 5.—The committee see strong objections to the wide powers given under this clause of the Bill for the registration of midwives who may represent themselves as at present engaged in *bona fide* practice. They consider that the conditions under which the registration of these persons should be permitted ought to be made much more stringent, or the register would be flooded with ill-educated persons. It is, in their opinion, important that certificates of character and of competency, as well as proof of occupation as a midwife, should be furnished by each candidate for registration under this clause.

"Clause 6.—That the Midwives (Midwifery Nurses) Board should have an official chairman, to be appointed either by the Lord President of the Privy Council or by the President of the Local Government Board. The committee consider that the Incorporated Midwives Institute should appoint only one representative on the Board, and that the Obstetrical Society of London should appoint a representative.

"Clause 8.—The committee consider that the fees named in this clause will not be sufficient to provide for the payment of the charges to be met by the Midwives (Midwifery Nurses) Board. They suggest that power should be given to the Board to fix the fees.

"Clause 16.—The committee ask the Council to point out to the Lord President that no similar provision exists in the Medical Acts for the prosecution of offences, and they venture to suggest that, if such provision is considered necessary, the consenting authority should be either the Registrar of the Midwives Board or the local supervising authority referred to in Clause 12."

Sir WILLIAM TURNER, commenting on the Bill and the report of the committee, said that if the former became law

it would give to midwives a legal status they had not hitherto possessed, and the qualifications of women to act as midwives would in future be tested by a statutory board. It followed, therefore, that the Bill was a most important one and required very careful consideration by this Council. It was quite possible that the Council might desire to make other amendments in addition to those proposed by the committee, and it would be open to any member to put such forward. As to the first recommendation, that dealing with the title of the Bill, the committee were almost equally divided. There was merely a majority of one for the conversion of the term "midwife" to "midwifery nurse." He was one of the minority, and if he, as chairman of the committee, moved the adoption formally of the first recommendation he must reserve his individual rights.

Sir WALTER FOSTER seconded the first recommendation. He yielded to no one in the desire that poor women should have competent treatment on the part of the midwives who attended them at their confinements, but he did not think that that would be facilitated by this Bill. Indeed, he feared that greater, and possibly more serious, evils might await them if this Bill were passed in its present form. Some time ago the following resolution was adopted on his motion—viz.: "That this Council regards the absence of public provision for the education and supervision of midwives as productive of a large amount of grave suffering and fatal disease among the poorer classes, and urges upon the Government the importance of passing into law some measure for the education and registration of midwives." In moving that resolution he was actuated by a desire to save poor women from endless suffering and from bad treatment at the hands of ignorant women who undertook to attend them during their confinements; but since that time they had received a large amount of evidence in connexion with the diplomas granted to some of these women, showing that these women with certificates or diplomas were guilty of the very practices they were then anxious to put a stop to. They had received evidence that these women disseminated puerperal fever and had been guilty of certain practices which were not at all desirable in the interests of the community. What he objected to about this Bill was that it would give to women (who were in no sense competent to undertake the sole charge of midwifery cases) a quasi-legal sanction, so that they would practically become practitioners of midwifery. He did not object to women becoming practitioners of midwifery, but he wished them to become so on the same terms as men. In the case of men knowledge of medicine and surgery, as well as of midwifery, was required by law for the practice of midwifery. The only limitation prescribed was the limitation of natural labour, but whether a labour was natural or not it required great command of knowledge for its treatment. There were many unqualified practitioners who were very skilful in attending midwifery cases, and surely, if the employment of one of these men was condemned by the Council, they could not admit a woman who had no knowledge of medicine or surgery and whose knowledge of midwifery was picked up in the course of a few months' instruction and attendance on a small number of cases. He would have nursing treated in all its branches and have properly trained medical and surgical and midwifery nurses and treat them all alike. The woman who attended poor people at their confinements should be as well educated as the surgical or medical nurse.

Mr. WHEELHOUSE supported Sir Walter Foster's view and the recommendations of the committee. At the present moment there was scarcely a village or hamlet throughout the length and breadth of the land where a qualified medical man could not be obtained either immediately or upon very short notice. In former times this was not the case. Moreover, there had been great changes in the law. No one could practise midwifery before he had passed a test in medicine and surgery as well as in midwifery. Further, the whole science of nursing had undergone an entire change in recent years. Nurses were now trained for all portions of their work, and they had trained medical and trained surgical nurses. Why should they not also have trained obstetrical nurses? And why, if the medical and surgical nurse was at all times to be kept in subservience to the medical man, should the obstetrical nurse be allowed by law to take the whole of his duties upon her own shoulders and without any control from him or anybody else be allowed to practise the whole art of midwifery? He did not think it right that they should constitute by statute a new order of practitioners.

Mr. TEALW said the Council were not asked to sanction or

approve a Bill for the creation of a new order of nurses. Nurses were not in question at all. They were asked to sanction a Bill for doing a certain thing in reference to a large body of persons who had been existing under this name from time immemorial, and who existed in this country at the present moment in very large numbers. He quite understood the fears of some medical men, but there was a demand here which must be met, and the Council would make a mistake if they tried to alter this name. Their better course was to endeavour to obtain suitable safeguards.

Dr. MACALISTER thought Sir Walter Foster was taking a sharp turn indeed when he asked the Council to ignore not only his own resolution of 1889, but to ignore their whole proceedings on this question. Absolutely nothing would be gained by anyone going through as many as ten and a half pages of this report to lead him to suppose that the first resolution of the Council would be one to substitute "midwifery nurse" for "midwives." Mr. Wheelhouse, he thought, had put the dots on Sir Walter Foster's "i's" when he indicated that what ought to be done was to change the title to a Bill for the abolition of midwives for the benefit of medical practitioners. To leave out "midwives" was to change the whole character of the Bill. Many of the midwives of the present day were uneducated, some of them were dangerous, and the question was whether they should be allowed to continue and whether or not the dangerous ones should be weeded out. The fact that they must keep in mind, and which seemed to have been constantly before the Council in connexion with its previous resolutions, was this—that women did help women in their labour, women might legally help women in their labour, and for doing so might at the present moment sue for their fees. They were under the law. Were they also to be supervised? Should they be registered? The Council wanted to raise their status by placing them on a register and making them liable to a penalty if they broke the conditions on which they were registered. They could not present such a resolution to the Government without stultifying themselves. If they agreed to recommend such a change—such an unwise change—some strong reason would have to be given for it. The only reason he could give for it was that a certain number of practitioners had agitated for it. He believed it was the opinion of the Council that supervision was absolutely necessary. If the abuses complained of could exist under the present state of the law, to ask that no law should be passed was to stultify their own position. They had to recognise the fact that midwives exist, and the question was whether, like plumbers and others, they should be registered. He objected to any change in the title of the Bill.

Dr. BRUCE did not know whether it was right for him to take part in this discussion seeing that the Bill did not affect Scotland, but if it passed for England and Wales the chances were that it would pass for Scotland also, and therefore he wished to take this opportunity of giving reasons in support of Sir Walter Foster's position on the subject. He did not think it was fair to say that because some of the Council did not approve of this Bill they did not approve of any Bill. He approved of the term "midwifery nurse," but this Bill did not meet the difficulty. The effect would be, instead of improving the kind of midwives, they would have women not one bit improved who thought themselves the equals of medical men. He did not think that a proper position for midwives. Those women must not assume themselves to be educated and of the same status as medical men. That would do a great deal of harm amongst the poor people they were anxious to protect. This Bill should be qualified as Sir Walter Foster had suggested, and the Council should take care that they put these women in a subordinate position. It would be doing a great injustice to the public if they gave the right to these women to practise midwifery. Their training was quite insufficient for that.

Dr. WILKS pointed out that if they adopted this recommendation they would be going back to the use of the word midwifery as a term including all the diseases of women. The word "midwives" was a simple one, known to everyone, and used from time immemorial to mean women attending women in the natural process of delivery. To use the term "midwifery nurse" would destroy the whole of the Bill.

Dr. MCVAIL said he was not in the Council when the resolutions embodied in the report were passed, but he saw no inconsistency whatever between these resolutions and the recommendations they were now asked to adopt. These

resolutions were resolutions in favour of the registration of midwives. He was perfectly satisfied there was no objection on the part of anyone to the registration of midwives. But what did this Bill mean by midwives? In what sense did it mean the registration of midwives? In 1886 they had no legal definition of "midwives." Midwifery in that year became one of the standing branches of the medical profession, and he believed that no man or woman could practise midwifery who did not know medicine and surgery as well. This Bill referred to a woman who attended cases without the direct supervision of a medical practitioner. That meant that a new class of practitioners was to be created, that midwife was to mean something else than it ever meant before. Were the Council prepared to advise the Lord President to support the Bill and introduce into this country a new class of practitioners who were to practise midwifery without the supervision of any medical man? That was the point. Clause 1 set forth that the midwife was a woman who attended a woman in natural labour. Would anyone define "natural labour." The clause did not attempt it, and he did not think any member of the Council would try, but these midwives of the Bill, this new independent class of practitioners, were to define what "natural labour" was. It would be possible under the Bill for a midwife to say, "I was engaged for a case of natural labour, and yours is not natural labour at all." Yet there was no provision in the Bill to meet such an emergency as that. If the Bill had provided that the woman was to be under the supervision of a properly qualified medical man, who could come to help her whenever she called him, he would be able to support the Bill, but it did not do that, and the recommendation was an attempt to get it into the mind of the Lord President that there should not be set up a new set of practitioners who were not only to attend natural labour but to define it.

Mr. BRUDENELL CARTER said that during the last twenty-five years the Council had been constant in pressing upon the Government the necessity for some measure for the better education and registration of midwives. He was not prepared to go back from that. He approved of the word "midwives" because he knew what it meant. He did not know what "midwifery nurse" meant. He knew that there were thousands of poor women throughout the country who were unable to pay a medical man's fee and were attended by midwives. Though difficult to define, the arrangement worked very well in practice so long as they found a midwife who was conscientious. The Bill contained nothing about midwives' education. That would be regulated by the Midwives Board, and no doubt would be improved in time. He thought the Council might fairly trust the Midwives Board to lay down such rules as would guard the public against the abuses at present complained of, and furnish a class of women on whose conduct in ordinary cases the public might safely rely. He believed the Council would be supported in proceeding on the lines of their action hitherto.

Dr. GLOVER did not think it would be right for them to part with the word "midwife," but he thought it should be made clear that the person who was called midwife was a midwife and a nurse and in that respect was differentiated altogether from the medical man. The midwife's value consisted, not only in delivering the woman, but in acting as her nurse for several days afterwards. To make it clear that she was not a medical practitioner, and was also a nurse, and at the same time to retain the old word that was so familiar to all, he proposed to substitute "nurse-midwife" for "midwifery nurse." He thought this might meet the approval of the Council, for, after all, the points on which they were not agreed were very small. At any rate, on this occasion he could not go back upon a resolution of his own embodied in the committee's report, nor could he dissociate himself from the long list of able members of the Council who had asked for legislation on this matter of midwives' education and registration.

Mr. BRYANT, in seconding the amendment, said he had some affection for the word "nurse-midwife," as he believed he was the introducer of it. He did not think they could altogether throw aside the term "midwife."

Dr. LOMB AITHELL said that in the Irish hospital which he is connected the equivalent term used for monthly nurse was "midwife and nurse." He held that every woman who was to have to do with women at their times of labour should be as carefully trained to be a nurse as to be a midwife, and every woman who was able to afford it should have such an attendant. He thought that the Bill would be a very valuable measure if properly amended, and one

amendment the Council should endeavour to obtain should be a provision under which women would be trained to be nurses as well as midwives.

After some remarks by Dr. LEECH,

Professor GAIRDNER said it seemed to him that the definition of the term "midwives" in the Bill would exclude the medical practitioner, for it would allow a woman to attend natural labour without the supervision of a medical practitioner. They must take that into account. The Bill was evidently intended to legalise a new class of practising women who would be independent of the medical practitioner, and he was therefore entirely in favour of the substitution of "midwives" by "nurse-midwife."

Sir WALTER FOSTER said it was intended, if the recommendation was carried, to move a further amendment placing the midwifery nurse under the direct superintendence of a medical man.

The Council proceeded to vote on Dr. Glover's amendment, with the result that 8 voted for it and 16 against it. Thereupon a vote was taken on the committee's recommendation, when 12 voted for the recommendation and 14 against it.

Sir WALTER FOSTER asked that the roll should be called. This was done with the same result.

The recommendation accordingly was rejected by a majority of 2. Dr. Glover declined to vote and Dr. Kidd was absent.

The Council adjourned at six o'clock.

TUESDAY, JUNE 4TH.

The Council met again to-day, Sir RICHARD QUAIN presiding.

Midwives Registration Bill.

The Council resumed in committee the consideration of this Bill and the report made upon it by the special committee.

Sir WILLIAM TURNER said that as they left the definition clause yesterday its first section ran thus: "The term 'midwife' means a woman who undertakes to attend cases of natural labour without the direct supervision of a medical practitioner."

Sir WALTER FOSTER moved to leave out "woman" and insert "person," in order that he might call the attention of the Council to the position in which they were placed by this Bill.

The PRESIDENT said he should like to have a clear understanding as to what they were about. They had been asked for their opinion with regard to this Bill by the Lord President. If they chose to say they had no opinion about it and desired none of it, that was another matter.

Sir WALTER FOSTER claimed to be allowed to discuss the Bill.

The PRESIDENT: Our duty is to the Government who ask us for our opinion.

Sir WALTER FOSTER: My duty is to my constituents.

Sir WILLIAM TURNER: I think Sir Walter Foster is perfectly in order.

The PRESIDENT: If Sir Walter Foster's amendment is carried there is an end to the report of the committee.

Dr. HAUGHTON: It appears to me that Sir Walter Foster is putting his finger on the very point we have to discuss. His amendment goes to the root of the whole Bill, and it will save time to have it discussed now.

Sir WALTER FOSTER then proceeded with his speech. He was anxious, he said, that women should have a fair field and no favour in the practice of the profession or any branch of it, and this Council very early in its career showed a laudable desire to remove restrictions upon the entry of women to the profession, and in accordance with that they now had women capable of becoming members of the profession just as men were after passing certain tests. This Bill, however, proposed to give women privileges over men. When a man got into general practice one of the first difficulties he encountered was the difficulty of attending midwifery cases. He used to be able to meet this with the system of pupillage and more recently with the employment of an unqualified assistant. The latter practice grew into an abuse because the registered practitioner got into the habit of setting up the unqualified assistant in a branch practice, and this Council had gradually brought that within the purview of their definition of covering. If this Bill became law they might very well have a condition of things in which all the resolutions of the Council with regard to covering could practically be set at naught. A medical practitioner instead

of employing a man as an unqualified assistant would employ one, two, or three of these women in different localities near his home, each having her name on her door as a registered midwife. These women would call in the practitioner when he was wanted for complicated cases, and transfer to him all the general practice arising out of the cases of midwifery. If, therefore, such a practice of midwifery was to be instituted he said it was only fair that men should share it with women. They were bound in common fairness to put men in as good a position as women.

Mr. WHEELHOUSE, seconding the amendment, said he did not see why they should take away from men a privilege which they had possessed for any number of years or why they should give the privilege to women alone. If they passed this amendment then they would have equality of treatment between the sexes.

Mr. TEALE could not believe that Sir Walter Foster was serious in bringing forward this amendment, because men could not in any sense be described as midwives. The idea of a midwife was a person who would not only attend the labour but remain afterwards to nurse the woman, and surely Sir Walter Foster did not propose the latter function for men.

Dr. MACALISTER said that until both men and women were subject to the attentions of midwives men and women were hardly on the same footing with regard to the duties and privileges of midwives. It was quite clear that Sir Walter Foster meant to destroy the Bill. His amendment was an ingenious one, but he hardly thought it would commend itself to the common sense of this Council.

Dr. GLOVER agreed that the object of Sir Walter Foster was to make the Bill ridiculous. If Sir Walter Foster held a brief for the unqualified assistants in this country he thought he should tell the Council; but that he should ask the Council to pass a resolution which would give them a function and standing and immensely enlarge the competition with the profession was asking them to believe either in their simplicity or his own. He (Dr. Glover) distinctly, in the interests of the profession, refused to open a door to let in, wholesale, uneducated men on the footing that the humble women contemplated by this Bill were to be admitted to practise midwifery. The necessity for this legislation arose distinctly from the tragedies that happened in the practice of uneducated women, and now it was proposed to admit an inferior class of general practitioners. This amendment asked them virtually to qualify and admit and recognise all the unqualified practitioners in the country, and he refused, and he hoped the Council would refuse, to do anything of the sort.

Dr. MCVAIL said he intended to vote for this amendment. Dr. Glover spoke about the Bill getting rid of the scandal of the tragedies connected with the practice of ignorant women, but the Bill proposed to license a certain number of women after going through some short course of study and submitting to some slight examination. If that were a right thing to do in the case of women it ought unquestionably to apply to men. According to the Bill, men who had studied anatomy, physiology, and the fundamental sciences of medicine, in a way that these women would never study them, would if they went before the proposed examining board be turned away and told, "Go and put on petticoats; it is not what you know that is to admit you, it is your sex." This state of things was preposterous.

Dr. BRUCE confessed that he would not be sorry to see the bottom knocked out of this Bill, because he considered it was essentially a bad Bill, and that we were not yet quite ripe for legislation on this subject.

On a vote being taken on Sir Walter Foster's amendment, 7 members voted for it and 21 against it.

Sir WILLIAM TURNER then moved in accordance with the recommendation of the committee to strike out all after the words "natural labour," and insert "but not to discharge any other duties than those of a midwifery nurse."

Mr. WHEELHOUSE seconded the motion.

Mr. BRUDENELL CARTER said that this amendment would prevent a woman performing any of the customary duties of social or domestic life. Under this definition of a midwife a woman could be a midwife but nothing else; she could not be a mother, a housewife, or a cook.

Dr. ATTHILL thought it was essential to the protection of the medical profession that there should be some definition of the legal duties of a midwife.

Dr. MCVAIL said that the best way to meet the difficulty was to say that a midwife meant a woman who undertook to

attend cases of natural labour "with the direct supervision of a medical practitioner."

Dr. HERON WATSON moved to substitute for "woman" the words "lying-in nurse."

This motion was negatived by 19 votes to 11.

Dr. MCVAIL asked whether in this instance Sir William Turner intended to vote for the amendment which he had moved.

Sir WILLIAM TURNER said he desired to hear the arguments before he committed himself.

Dr. MACALISTER, seconded by Dr. CHURCH, moved to add after "natural labour" the words "and to nurse lying-in women."

This motion received 10 votes, while 14 members voted against it.

Mr. TEALE suggested that a way out of the difficulty would be to add the words "subject to the restrictions and regulations made by the Board provided under Clause 6."

Sir WILLIAM TURNER did not think there was any necessity for these words, because it followed that midwives must be subject to the provisions of the Act.

Dr. GLOVER thought there could be no harm done by inserting the words, which certainly emphasised the limitation.

Dr. KIDD pointed out that there was no definition of natural labour.

Dr. MCVAIL, seconded by Dr. HERON WATSON, moved to add after "natural labour" the words "under the supervision of a regular medical practitioner." Dr. McVail explained that he only meant this to pave the way for other alterations to be proposed later.

The motion was rejected by 14 votes to 9.

Dr. KIDD, seconded by Dr. WILLIAM MOORE, moved to insert these words: "That for the purposes of this Act the term 'natural labour' means labour completed within twenty-four hours of the commencement."

Mr. TEALE thought it was most undesirable to stereotype any definition of natural labour.

This motion only received the support of the mover and seconder.

Dr. MACALISTER, seconded by Dr. GLOVER, then moved that the definition of "midwife" stop at the words "natural labour."

This was carried as an amendment by 20 votes to 7.

On it being put as a substantive motion,

Dr. MCVAIL objected to it. In this form the clause was in his view an absurdity. They had not defined and they could not define natural labour; yet this clause meant that they had defined it.

Dr. MACALISTER said that the object of the Bill was to make the scope of the law as wide as possible, so as to bring within it the largest possible number of the present unqualified and uncontrolled midwives; therefore, the wider they made the definition the better.

The amendment of Dr. MacAlister put as a substantive motion was then carried by 20 votes to 5.

No objection was taken to the definitions in the Bill of "Midwives Register" and "Midwives Board"; and Clause 3, which sets up registration, was also accepted after being altered by the substitution of "registered" for "legally qualified." On Clause 4 of the Bill, Sir WILLIAM TURNER said this clause was a very important one, because it laid down what were the privileges of registration under the Act. It was as follows:—

"A woman registered under this Act shall be entitled to act as a midwife in England and Wales. From and after the first day of January, 1896, no woman shall be entitled to recover any fee or charge in any court for attendance or service rendered as a midwife unless such woman be registered under this Act, and the certificate of registration under this Act shall be a certificate entitling a woman to act as a midwife in cases of natural labour only, in accordance with the prescribed regulations made in pursuance of the terms of this Act. A certificate under this Act shall not confer upon any woman any right or title to be registered under the Medical Act, 1858, or the Acts amending the same, in respect of such certificate, or to assume any name, title, or designation implying that she is by law recognised as a licentiate or practitioner in medicine or surgery or that she is qualified to grant a certificate of death or of stillbirth."

On this clause, as would be seen from their report, the committee had suggested certain amendments. The first of these related to midwifery "as defined in this Act." He was afraid that could not now stand, seeing that the Council had rejected the proposed term "midwifery nurses," and as apart from the proposal to introduce that term the term midwifery did not occur in the Bill.

Sir WALTER FOSTER said that the Bill disclosed its object

here. It intended that these people should be practitioners—practitioners in midwifery. He suggested the withdrawal of the committee's proposed amendment as being no longer of use for the purpose for which it was framed.

The amendment was not pressed.

Dr. GLOVER suggested that the latter part of the clause should be so altered as to provide that the woman certified under the clause should have no right to assume any name, &c. implying that she was a licentiate or practitioner in medicine, surgery, or midwifery under the Medical Acts.

Some discussion favourable to this proposal ensued, and ultimately it was agreed that the part of the clause affected should read as follows: "Implying that she is by law recognised as a practitioner in medicine, surgery, or midwifery entitled to be registered under the Medical Acts."

Sir WILLIAM TURNER then moved the other amendment suggested by the committee—viz., "If any such name, title, or designation is assumed, or if any certificate of death or of stillbirth be granted, the midwife on conviction should be subjected to a fine not exceeding —."

Mr. BRUDENELL CARTER thought it would be a mistake to introduce the term "stillbirth" into the Bill. It would be better to say "cause of death." He believed stillborn children were constantly being buried on the certificate of the nurse.

Dr. ATTHILL agreed. Midwives would from time to time have stillbirths, and they were the only persons cognisant of them. He, however, was against midwives having the power to give a certificate of death, but unless there was some prohibitory enactment the existing practice would continue.

Dr. GLOVER thought the words were very valuable, and he hoped they would be maintained. They all knew that one of the scandals of the times was the large number of stillbirths that were certified by midwives. They were told the other day that the number amounted to 45 per cent. of the whole.

Dr. HERON WATSON took the view that what was to be guarded against was the midwife giving a medical certificate. That could be secured by the insertion of the word "medical" in the last line of the clause.

Sir WILLIAM TURNER said the point that was really before the committee was that there should be a penalty.

Dr. MACALISTER pointed out that there were penal clauses in the Bill, and if it was now wanted to introduce a penalty that should be done later, after Clause 14. He suggested that if further alteration was made in the clause it should be to provide that midwives with certificates were not legally qualified under the Medical Acts to grant any medical certificate as to the cause of death.

Dr. CHURCH said he had been on the point of making a similar suggestion. He had been going to propose too that the words "or of stillbirth" should be left out of the last line of the clause, and that the ending should be "or that she is qualified to grant any medical certificate or any certificate of the cause of death."

Sir WALTER FOSTER reminded the Council that under certain Acts of Parliament certificates would probably be wanted that a woman had been confined, and the midwife would be able to give a certificate to that effect.

Sir WILLIAM TURNER said he would withdraw the committee's recommendation and accept Dr. Church's.

The Council agreed. On Clause 5, provision for existing midwives,

Sir WILLIAM TURNER said this Clause 5 was as follows:—

"Any woman who at the passing of this Act is in *bona-fide* practice as a midwife, or has obtained a certificate in midwifery from some hospital or workhouse infirmary, or from the Royal College of Physicians of Ireland, or from the Obstetrical Society of London, or such other certificate as may be approved by the General Medical Council, and claims to be registered before the expiration of two years from the passing of this Act, and produces the prescribed evidence of her title to be so registered (such title to be determined by the General Medical Council), shall be entered on the Midwives Register at such reduced fee as the Midwives Board shall prescribe."

He said that this was a clause to preserve existing rights, and the Council would see at once that it would sweep in a very large number of persons, some of whom might be fairly qualified and others of whom might have very small qualifications. The committee had felt that it was too wide and that it ought to be restricted. The Council had had considerable experience of existing rights in connexion with the Dentists Act. That was so wide that it permitted almost every man who had ever drawn a tooth to claim registration, and the result was that they had to put on the Dentists Register nearly 5000 names. The question was whether in connexion with the registration of midwives there

should be some preliminary investigation as to competency. He believed it was the practice in country districts of Scotland for women to be attended by their neighbours in the cottages near, women of absolutely no education at all. So long as the labour was natural there was no harm, but should not the Council now recommend that this clause should be made more restrictive? The committee had not specified precise amendments on the clause, which, in fact, would need entire reconstruction. They had contented themselves with a general statement of the matter, which hardly amounted to a recommendation. In connexion with that he desired to call attention to extracts from the minutes of the Council which formed an earlier part of the committee's report. These showed that the Council had always recommended that there should be certificates of character exhibited before registration. The Bill, strangely enough, omitted any reference to certificates of character, which, in a matter of this kind, the committee thought ought to be made imperative. He moved that the recommendation—if he might so call it—should form part of the Council's statement to the Lord President so that those interested in the passing of the Bill might see what their opinion was.

Dr. HERON WATSON thought that as the Council had the whole Bill in their hands it was for them to determine what should be the regulations under which these women were to be set up as registered midwives.

Dr. MACALISTER believed the last Midwives Registration Bill was wrecked in the House of Commons because it was proposed to insert a clause that a midwife should have a certificate from a clergyman. The titles were to be determined by the Council, and it would cover what certificates were required preliminary to registration.

Sir WILLIAM TURNER said that if it was the opinion of the Council that the Bill already gave sufficient power to the Council to require proper evidence of character he should not press his proposal.

Dr. ATTHILL thought there could be no objection to the recommendation going to the Lord President.

Dr. GLOVER did not see that any harm could result from taking the opinion of the Council on the recommendation.

The PRESIDENT then put the question, and it was adopted as part of the Council's statement to the Lord President.

Sir WILLIAM TURNER then read the following part of Clause 6:—

"Within six months from the passing of this Act a Midwives Board shall be formed, which shall consist of twelve registered medical practitioners, three to be appointed by the Royal College of Physicians of London, three by the Royal College of Surgeons of England, three by the Society of Apothecaries, and three by the Incorporated Midwives Institute. One-fourth of the members of the Board shall annually retire, but shall be eligible for re-election after the lapse of one year."

He said the committee recommended important amendments on that. Before proceeding to them he wished to remind the Council that this Bill applied to England and Wales only, and therefore the Midwives Board it proposed to constitute was exclusively formed by certain bodies in England. The committee did not wish to alter the number of practitioners on the Board or the numbers to be appointed by the bodies named, with the exception of the Incorporated Midwives Institute. They did not know anything about the Institute, and they did not know by what right it was to be put on the same footing as those other medical authorities. The Council knew those other authorities as consisting of the great body of the profession in England, but they knew nothing whatever about the Incorporated Midwives Institute. Therefore it was that the committee suggested an alteration of the proposed constitution. They proposed that there should be an official chairman, appointed either by the Lord President of the Privy Council or by the President of the Local Government Board. That chairman should be one of the twelve medical practitioners. They further proposed that the Obstetrical Society of London should appoint one representative, and thinking that this Incorporated Midwives Institute might be an institute which had certain good qualities although it was unknown to them they suggested that it should appoint a single representative. The Board would thus consist of three from the Royal College of Physicians, three from the Royal College of Surgeons, three from the Society of Apothecaries, one from the Midwives Institute, one from the Obstetrical Society, and the chairman.

Dr. BRUCE thought that, as this whole matter was a woman's matter, it should be left to the women. If a board was to be constituted at all it should consist of women.

Dr. CHURCH asked if the committee could not give the

Council a little light about the Midwives Institute. If they recommended even one representative from it they were recommending a society of which the Council knew nothing. The composition of this Midwives Board was the most important and most serious thing in the Bill, and when this Midwives Institute came into the question he felt in a difficulty.

The PRESIDENT pointed out that the existence of such a body as the Midwives Institute was recognised by the Bill having been read a second time in the House of Lords. The Bill originated with the Institute.

Dr. ATTHILL supposed that the Institute was a self-elected body.

Sir DYCE DUCKWORTH: Can no one tell us anything about this Institute? Is it composed of women or obstetrical practitioners?

The PRESIDENT: I do not know. I believe the Bill originated entirely with the Institute.

Sir DYCE DUCKWORTH remarked that in the correspondence the Council had before them a week ago there was a letter from a Midwives Institute having its office in Buckingham-street, Strand. When, he asked, did they become incorporated?

Professor GARDNER: Represent to the Privy Council that the General Medical Council know nothing about this body.

Dr. GLOVER did not think it was any essential part of their duty to make inquiries about this Institute. He saw from a Blue-book he had in his hand that a Mrs. Smith, treasurer, in giving evidence before the Select Committee, stated that this Midwives Institute was the only incorporated body of midwives.

As no further information appeared to be forthcoming,

Dr. ATTHILL moved that the Council was of opinion that the Midwives Board should consist of ten registered medical practitioners, nine to be elected in equal proportions by the Royal Colleges of Physicians and Surgeons and the Apothecaries' Society, the chairman to be appointed by the Lord President of the Privy Council or the President of the Local Government Board, and that one-third of the members elected by the medical corporations should retire annually.

Mr. BRUDENELL CARTER seconded this proposal, which was at once agreed to.

On consideration of that part of the clause relating to the duties to be performed by the Midwives Board, all the sections were passed without amendment with the exception of that providing for the filling of casual vacancies. This was struck out, and the preamble of the clause altered to enact that casual vacancies should be filled by the bodies who originally appointed. On Clause 7 an amendment was agreed to providing that the Midwives Board should draw up a form of certificate to be granted to midwives for approval by the General Medical Council. On Clause 8, "fees and expenses,"

Sir WILLIAM TURNER said the committee had gone into this clause very carefully, and the unanimous feeling was that the fees specified in the clause would not turn out to be sufficient for the purpose of working the Act. It was proposed that these fees were to be used to pay all the examiners, all the expenses of the Board, the secretary, and all clerical and other expenses. Besides, there were the medical officers of health, who were to have the supervision of these midwives. There were many outlets for the money for which these fees had to provide, and the feeling of the committee was that the amount of the fee should not be fixed by Act of Parliament. It was a dangerous thing to fix a fee by Act of Parliament, for if it was found that the fee was not sufficient Parliament would again have to be applied to. Therefore, they recommended that the Midwives Board should fix the fees in the first instance, perhaps getting the Privy Council's approval of them. The fees as specified were, at any rate, altogether inadequate, and it would be most unwise to fix the fees in an Act of Parliament.

The PRESIDENT wished the Council to remember that these poor women had not much means, and there should be some representation by this Council on the subject.

Mr. BRUDENELL CARTER suggested that Sir William Turner should draft a paragraph calling attention to the subject.

Sir WILLIAM TURNER said he would bring up one on report.

Clauses 9, 10, 11, and 12 were gone through, but no alteration was made. Dr. CHURCH, however, suggested that the initial register should be prepared under the direction of local bodies, such as the county councils.

Further consideration was put off till Wednesday, and the Council adjourned about six o'clock.

WEDNESDAY, JUNE 5TH.

The Council met again to-day with Sir RICHARD QUAIN in the chair.

Midwives Registration Bill.

The Council went into committee and resumed the consideration of this Bill and the report of the special committee upon it.

Sir WILLIAM TURNER called attention again to Clause 12, which proposes that the medical officer of health shall supervise the midwives in his district, and invited Dr. Thorne Thorne to express his opinion with regard to it.

Dr. THORNE THORNE said that of late years there had grown up a habit of imposing upon medical officers of health duties which they never undertook to perform, which did not properly belong to them, and for which they were either not paid at all or most inadequately paid. As to this clause he quite recognised that the medical officer of health was the proper man for the proposed work, for which he was eminently qualified. They had some 1100 or 1200 medical officers of health in England, and of these at least 900 were engaged in the practice of midwifery as well as of surgery and medicine. At the present moment the medical officer of health was the only man in the district who received any notice as to puerperal fever because he received the notice under the Infectious Diseases Act, and having received this notice he very often told the nurse that she had no right to take any more cases. But the woman snapped her fingers at him and went on attending fresh cases. With this Bill the medical officer of health would receive considerable powers and he made little doubt that he would be able to prevent a good deal of puerperal fever. He did think, however, that this important duty should not be imposed without adequate remuneration, and he proposed that the portion of the clause dealing with this matter should run thus, viz.:—"Such medical officer of health, or, in case either he shall decline the office or the local authority shall otherwise determine, such other registered medical practitioner as the local authority may appoint shall be the local supervising authority over midwives in his district." There was another point to which he wished to call attention. If it were true that the Midwives Board was not likely to have very large resources, it would be a great strain upon it to supply the 1100 or 1200 medical officers of health in the country with a free register every year, and he thought it would be a great waste of money. He was inclined to support the idea that some other body ought to keep the register.

The proposal made by Dr. Thorne Thorne was seconded by Dr. Bruce, and on being put to the Council was agreed to unanimously.

In connexion with the clauses providing penalties for offences, Dr. ATTHILL suggested that a midwife giving a document certifying or purporting to certify the cause of death should be subject to a penalty.

Dr. THORNE THORNE pointed out that anybody could give a certificate of the cause of death, and it was for the Council to consider whether these women should be placed in a singular position.

Clause 16 provides that "any offences under this Act punishable on summary conviction may be prosecuted and any fine under this Act recoverable on summary conviction may be recovered in manner provided by the Summary Jurisdiction Acts. A prosecution for an offence under this Act shall not be instituted by a private person except with the consent of the Attorney-General, but may be instituted by a county council or the council of a municipal borough. The expenses of any prosecution shall be defrayed out of the county fund of the district where the prosecution takes place."

Sir WILLIAM TURNER said that in this connexion the committee asked the Council to point out to the Lord President that no similar provision existed in the Medical Acts for the prosecution of offences, and they ventured to suggest that if such provision was considered necessary the consenting authority should be either the Registrar of the Midwives Board or the local supervising authority referred to in Clause 12.

The Council decided that this should be done.

Sir WILLIAM TURNER, on the last clause, which provides that the Act shall not extend to Scotland or Ireland, said

that such an amendment as Dr. Kidd had given notice of to amend Clause 4 by the omission of "England and Wales," and putting in place of these words "Great Britain and Ireland" would hardly be applicable. He did not think Dr. Kidd would allow that the whole of the administration of midwives in Ireland should come under a Midwives Board sitting in England and on which there was no Irish representative.

Dr. KIDD said he should be very sorry to see it.

Sir WILLIAM TURNER: But if your amendment were carried that would be the result.

Dr. KIDD: I thought the Bill would be altered.

Sir WILLIAM TURNER: With the entire reconstitution of the Midwives Board.

Dr. KIDD: I withdraw.

Sir WILLIAM TURNER, in then moving that the Council resume, suggested that some of the other business on the paper should be proceeded with while the report of the proceedings in committee of the whole Council was being prepared.

Rearrangement of Committees.

On the Council resuming Sir DYCE DUCKWORTH moved: "That Section IX. of the Standing Orders be amended so as to read:—'IX. Committees for Education, Examination, Public Health, Dental Education and Examination, and Students' Registration Committees. 1. Five committees shall be appointed, the first to be termed the Education Committee, which shall consider and report on all matters concerning preliminary general education and examination, the registration of medical students, and the course of professional study; the second to be termed the Examination Committee, which shall consider and report on all matters connected with professional examinations and with the inspection and visitation of these examinations; the third to be termed the Public Health Committee, which shall consider and report on all matters connected with the courses of study and examination for diplomas in public health and State medicine; the fourth to be termed the Dental Education and Examination Committee, which shall consider and report all matters connected with professional dental examinations, and with the inspection and visitation of these examinations; the fifth to be termed the Students' Registration Committee, to consider and report upon all doubtful cases for registration which may be referred by the several registrars.'" Adverting to the circumstances that had led to this proposal, he said that as times went on the business of the Council increased more and more, the work of the committees became heavier and heavier, and the duties the Council were called upon to perform also increased from year to year. As chairman of the Examination Committee he could say that the duties of that committee for the last three years had been very heavy indeed. These duties had been increased by the addition of the work thrown upon the committee in connexion with the inspection of examinations in public health and the inspection of the examinations in dentistry. It was thought that there should now be a special committee for Public Health, and the present was a suitable time to set it up now that the Council numbered among its members such an authority upon the subject as Dr. Thorne Thorne. In regard to the Students' Registration Committee it was thought the time had come when the committee should be placed under standing orders as a recognised committee of the Council. There was already a Dental Committee, but the Dental Examination Committee proposed to be set up was a special committee for a special purpose. It was proposed that the first three committees—the Education, Examination, and Public Health Committees—should consist of nine members each. The other two committees might be constituted with fewer members. Out of the thirty members forming the Council there were some who were not very busily engaged in the committee work, and it was proposed in this rearrangement to enlist the services of such. If the Council consented to the motion he believed the work of the Council would be more efficiently carried on and there would be less strain on the committees.

Dr. BARRY TUKE, in seconding the motion, proposed that the first three committees should consist of nine members each, three from each division of the kingdom, with power to appoint a chairman and subcommittees; and that the Dental Examination and Students' Registration Committees should consist of six members each.

Mr. TEALE proposed that the Public Health Committee should consist of six members.

This was seconded by Dr. BRUCE, but on a division was rejected by twelve votes to eight. Sir Dyce Duckworth's motion as modified by Dr. Tuke's proposal was then carried unanimously.

Sir DYCE DUCKWORTH remarked in answer to a question that it was not necessary to fix a quorum. The members of the Council's committees attended excellently well, and outsiders were not aware of the great quantity of work that was done in these committees. The Council's work could not be judged by only what took place around the table they were sitting at, because the heaviest, gravest, and most important issues that the Medical Council had to decide were dealt with in committee.

Appeal of Mr. R. M. Theobald.

The Council next gave consideration to the following part of the agenda paper:—

"Appeal from Mr. R. M. Theobald against the decision of the Executive Committee, according to which he was informed that the application for the restoration of his name to the Medical Register—like all such applications—could be considered at the November session of the Council only. Mr. Theobald urges that the reconsideration of his case is urgent, inasmuch as he regards the whole process that resulted in the erasure of his name as utterly irregular in an unexampled degree."

On the suggestion of the PRESIDENT and the formal motion of Dr. MACALISTER, the communications in respect to this matter were referred to Mr. FARRAR, the Council's solicitor.

Finance.

Mr. BRYANT moved the adoption of the report by the Finance Committee. This showed that the income of the General and Branch Councils for the year ending Dec. 31st, 1894, had been £8957 11s., an amount which was £730 7s. 10d. less than the income for the year 1893. The fees received by the English Branch Council in 1894 were £197 12s. 6d. less than those received in 1893; those received by the Scottish Branch Council in 1894 were £380 12s. 6d. less than those received in 1893; while the receipts of the Irish Branch Council from registration fees during the same period showed a decrease of £96 15s. against those received in 1893. The expenditure during the year 1894 had been £9449 9s. 6d., an amount less than that of 1893 by the sum of £301 19s. 8d. A comparison of the income with the expenditure showed that the expenditure during the past year had exceeded the income by the sum of £491 18s. 6d. The receipts and expenditure of the Dental Registration Fund showed that the receipts amounted to £676 13s. 11d., showing an increase of £62 18s. 7d. on those of 1893, which were £613 15s. 4d. On the other hand, the expenditure had been £521 16s. 6d., being less than the income by the sum of £154 17s. 5d. The report, Mr. Bryant thought, would be regarded as a satisfactory one. They were paying their way, and although the balance was not increasing very rapidly, still there was a balance.

Sir DYCE DUCKWORTH seconded.

Dr. BRUCE asked if, with deficiencies in income in both 1893 and 1894, the Council really were paying their way.

Mr. BRYANT replied that in these two years the Council had had to meet extra expenditure which would not continue. For ordinary purposes they certainly were paying their way.

The report was adopted.

Midwives Registration Bill.

Sir WILLIAM TURNER brought up the report on this Bill. He also brought up a new recommendation in regard to Clause 8. The latter, after some conversation, was adopted in the following form:—The Council would suggest to the Lord President that the fees to be paid to the Midwives Board should not be fixed in the Act. It seems desirable that the Midwives Board should be authorised to fix the fees, subject to the approval of the Privy Council. It should also be pointed out that the General Medical Council, as the supervising authority for the Midwives Board, will require to devote during each session a portion of its sittings to the business of that Board, and will incur expense in connexion therewith. As the funds of the Council consist solely of the fees paid by medical practitioners for admission to the Medical Register it does not seem to be equitable that they should be expended upon work imposed upon the Council in connexion with the Midwives Board. Further, the practitioners in Scotland and Ireland would contribute to the expenses of an Act applicable only to England and Wales. The Council would point out that, as the Bill has been introduced in the

interests of the public and as midwives are not in a position to pay large fees for purposes of registration, a grant should be made by the Treasury to meet the expenses of the Midwives Board and the additional charges imposed on the General Medical Council.

Dr. WILKS asked the Council to receive information about the Incorporated Midwives Institute. So far as he could understand the institute was a highly respectable institution, managed by a committee including the Governor of the Bank of England, Members of Parliament and well-known benevolent ladies of London. Dr. Thorne Thorne had been making inquiries and could give more information about it.

Dr. THORNE THORNE said that on the previous day he felt rather troubled when he found the Council had erased from the Midwives Board every single woman, and had put on only men to control these women. He thought that might be misinterpreted out of doors. It might be thought the Council had decided that women should be put entirely aside in respect to this matter. The only reason given for ignoring this Midwives Institute—the only women's body—was that they did not know the institute, and he had made inquiries. He found that the institute was founded in 1881 and got a charter in 1891. There was a Royal Princess at their head, a committee composed as Dr. Wilks had said, and a number of respectable people connected with it. Such being the case, it would be very improper that this Council should erase the name of the institute from the Bill on the ground merely that they had never heard of it. If there was any body of women who had a right to be placed under this Bill it was a body of the sort that the institute was composed of. He, therefore, proposed that Clause 6 of the Bill, as altered on Tuesday, should be further altered to provide that the Midwives Institute should have three representatives—three female practitioners—on the proposed Midwives Board. He was not giving women a high position. Even with the representation he proposed they would be in a minority of three in a board of thirteen.

Sir DYM DUCKWORTH did not think the question of sex was before the Council on Tuesday at all. What caused him to vote as he did was the fact that the Medical Council had not hitherto recognised private societies or incorporated bodies except the universities and those great corporations qualified under the Medical Acts. Of the latter they were quite sure, of others they were not sure.

Professor GAIRDNER pointed out that Clause 7 of the Bill provided that, failing the Medical Council, the Privy Council should invite some other body to undertake the duties. He thought they should take advantage of that provision, wash their hands of the whole Bill, and let the Privy Council get some other body.

Mr. CARTER considered Dr. Thorne's proposal to give the institute representation by female practitioners was calculated to add a new terror to the male members of the Midwives Board. He had had some experience of a mixed board lately, and he sincerely trusted that experience would not be enlarged.

Sir WILLIAM TURNER was of opinion that Dr. Thorne ought to give the Council some assurance that this Institute possessed something of the elements of permanency. He had entertained from the first a strong objection to putting this society, that had been incorporated only four or six years, upon the same footing as those historical and most important institutions with which they were acquainted and which played so large a part in connexion with the medical profession in England and Wales.

The PRESIDENT said he believed that the Bill originated entirely with the institute. To leave out the authors would be something like leaving the Prince of Denmark out of the play of "Hamlet." He thought they should put back the constitution that was originally in the Bill.

Dr. GLOVER: Do I understand that all the ladies to be elected are to be members of the medical profession?

The PRESIDENT: Yes.

On the question being then put, Dr. Thorne's motion was carried by 14 to 10.

On the motion of Dr. ATTHILL, seconded by Dr. KIDD, it was agreed to recommend that the title of the Bill should be "A Bill to Promote the Better Training of Women as Midwives and Midwifery Nurses and for the Compulsory Registration as such." It was further agreed, on the motion of Dr. MACALISTER, to recommend that the Bill should explicitly provide punishment for persons registered under it who illegally assumed a title, improperly granted a certificate of death or infringed the rules of practice approved by the

General Medical Council. Clause 5, moreover, was altered so as to prevent any particular hospital being named.

There being no other amendments,

Sir WILLIAM TURNER moved that the communication to the Lord President in reply to his request for the observations of the Council on the Midwives Registration Bill should consist of two parts: (a) the report of the Committee, omitting the recommendations, and (b) the resolutions which the Council had adopted.

Mr. TEALE seconded the motion.

Sir WALTER FOSTER moved as an amendment that the answer to the Lord President should be that the Council, while desiring to improve the education, training, and control of midwifery nurses, could not support the Bill for the Registration of Midwives now before Parliament, inasmuch as that Bill would give a legal status to women who are not properly qualified to take sole charge of midwifery cases; but should the Bill be proceeded with the Council considered that it should be amended according to the report and resolutions. He thought the preamble to this proposal was necessary not only for the honour of the Council but for the safety of the public and the interests of the medical profession. They were in a difficult position. It would be known in both Houses of Parliament that the Council had been engaged for three days discussing a Bill which was the Bill of a private member of the Upper House, which was the product of a somewhat small and obscure body called the Midwives Institute, and which had not been brought before the Council by any of the great bodies with which it was associated, but was opposed by a large number of the medical profession. If the Bill went back unaccompanied by his motion, it would be said that it was no longer the Bill of Lord Balfour of Burleigh, but was a Bill amended by the General Medical Council. It would have a sanction and authority it never could have had if it not been discussed here. He thought the whole Bill was bad. It would be dangerous inasmuch as it would create a new class of practitioners; it would be dangerous because it was calculated to increase the number of what they were in the habit of calling unqualified persons. It would menace in that way the discipline the Council exercised over the profession. He believed it would be a danger to the public interest, inasmuch as many who had carried on objectionable practices in the past would be able to get on the register, and in their new position continue to carry on these practices. If they introduced a class of persons who must be imperfectly educated they endangered the public health. Let the Council qualify their opinion of the Bill by passing his proposal so that they might not mislead the Government on the one hand, and the public and the House of Commons on the other, by expressing their approval of a measure that would be dangerous to the public health, injurious to the medical profession, and not conducive to the morality and well-being of the public.

Mr. WHEELHOUSE seconded the amendment.

Dr. MACALISTER thought the position of the Council very grave in a direction other than that present to the mind of Sir Walter Foster. They were entrusted by the Lord President, the official representative of the Government, with the privilege of discussing and making observations on the Bill. That he took to be a considerable compliment, and it would ill become them to answer cavalierly. If they returned the answer Sir Walter Foster proposed he ventured to think they might expect to never have another Bill submitted to them. The Council had been consistent up till this session on the subject of the registration of midwives—not midwifery nurses. They had been agreed that the practice of midwifery in the ordinary sense required close supervision and control, and to return an answer of the kind proposed by Sir Walter Foster would be to stultify the Council, and make it appear that their opinion, when at a pinch the Government wanted it, was one not to be depended upon. He trusted they would stick to what they resolved in the motion proposed by Sir Walter Foster in 1889 and agreed to by the Council, namely:—

"That this Council regards the absence of public provision for the education and supervision of midwives as productive of a large amount of grave suffering and fatal disease among the poorer classes, and urges upon the Government the importance of passing into law some measure for the education and registration of midwives."

The Government had that resolution and asked on the first opportunity the opinion of the Council upon a measure on the subject. Their answer ought to be carefully weighed

and not to be evasive, as it would be if they were to return the answer that Sir Walter Foster now proposed to send.

Dr. GLOVER, keeping himself in the old lines, wanted the Council to remember that the object for which legislation was desired was, in historic words, "the protection of women from the incompetent." That was the object of the Bill they had been discussing. There was no question that it was wanted. There was no use of saying that a little knowledge was a dangerous thing, for the Bill was an attempt to abate the evil of the little knowledge. They did not need to go far afield to seek proof that women with such training as was contemplated in this Bill were in ordinary cases safe practitioners. They had it in the statistics of a London institution where only two deaths had occurred in 1600 cases. All Sir Walter Foster's arguments were directed not against this Bill only but against all Bills. In so far as that was so, Sir Walter Foster was in the minority, for the profession generally were agreed that there must be some legislation.

Sir WALTER FOSTER said he had been prepared to accept this Bill if "midwifery nurses" had been put in the place of "midwives."

Dr. GLOVER wanted to know how they were to go on for twenty years more insisting that the matter was urgent, while when a Bill came before them they rejected it. The position of the Council was indeed a grave one, for if they did what Sir Walter Foster wanted them to do they should be discredited as an advising body guiding the medical profession. He hoped the Council would give the Bill as amended by them a very hearty support.

Dr. MCVAIL said that if his views on Tuesday were the same as those of Sir Walter Foster they were much more so on Wednesday. As a Crown representative he was going to vote for Sir Walter Foster's resolution, and he only regretted that it was not stronger than it was. Had the Bill been amended so as to put these women under medical men of competence he should have had no hesitation in allowing it to go, but they were saying to the Lord President "You may pass this Bill and authorise women to attend natural labour—which no one could define—without the supervision of a medical man." The Bill was so entirely bad that he had no help for it but to vote for the amendment.

Dr. BARRY TUKES said they must guard against an attempt to kill all such bills as this one not in the interests of the women who suffered but in the interests of a small and inconsiderable part of the medical profession.

Mr. BRUDENELL CARTER held the Bill to be a beginning in the right direction, and he hoped the Council's action would be sustained by a large majority.

The PRESIDENT said that the question had been before them for three-and-twenty years, and he did not see any action to take better than that expressed in Sir Walter Foster's own resolution of 1869. He thought in that Sir Walter Foster answered himself.

Sir W. FOSTER: Is it not possible that a man may grow wiser?

Dr. HAUGHTON: Quite possible, but very rare.

The PRESIDENT: We have spent three days on this matter, and I hope the recommendations of the Council will be carried by an overwhelming majority.

Sir PHILIP SMYLY: Are the Irish and Scotch members expected to vote? They are not interested in the Bill at all.

The PRESIDENT: Certainly.

On the vote being then taken, the amendment was defeated by 18 votes to 7 and Sir William Turner's proposal carried by 23 to 6.

After appointing the Executive Committee, the Council adjourned at 6 o'clock.

Medical News.

UNIVERSITY OF LONDON.—The following candidates have passed the M.B. Examination for May, 1895:—

FIRST DIVISION.

Harvey, John Owen, St. Bartholomew's Hospital.
Hickinbotham, James Hyland, Mason College and General Hospital, Birmingham.
Pollard, Walter Henry, St. Bartholomew's Hospital.
Rigby, Hugh Mallinson, London Hospital.
Tait, Archibald, Yorkshire College and General Infirmary, Leeds.
Turner, William, King's College.
Walt, Joseph Edward, University College.

SECOND DIVISION.

Branson, Guy Joseph, B.A., Mason College.
Burnett, Frank Marsden, St. Bartholomew's Hospital.
Cochrane, Archer William Rosa, St. Bartholomew's Hospital.
Elliot, William Henry Wilson, Guy's Hospital.
Fenwick, Percival Clennell, St. Thomas's Hospital.
Gostling, George Wilfrid, University College.
Horner, William Ernest Leethem, University College.
James, Sydney Price, St. Mary's Hospital.
Jones, Richard Llewellyn, University College.
Knight, Harriet Edith Florence, London School of Medicine and Royal Free Hospital.
Mace, John, Yorkshire College and General Infirmary, Leeds.
Mantell, Hugh Fraser, St. Mary's Hospital.
Martin, Antony Alexander, St. Mary's Hospital.
Miskin, Leonard John, St. Thomas's Hospital.
Norrunn, Richard Henry, Westminster Hospital.
Oldfield, Carlton, Yorkshire College.
Richmond, Benjamin Arthur, B.Sc., Guy's Hospital.
Roberts, Cecil David Dale, Mason College and General Hospital, Birmingham.
Slater, George Nathan Osceot, St. Bartholomew's Hospital.
Sly, Edwin, King's College.
Starkey, Thomas Albert, University College.
Steinhäuser, John Robert, Guy's Hospital.
Swatman, Helen, London School of Medicine and Royal Free Hospital.

UNIVERSITY OF EDINBURGH: FACULTY OF MEDICINE.—The following candidates passed the First Professional Examination, March, 1895:—

Old Ordinance.—W. H. Dawson, M.A., M. L. Dhillra, Miss A. M. C. Giddes, D. J. Head, D. J. Hughes, B. E. Myers, R. M'K. Sinner, and John Vane (passed in July, 1894).

New Ordinance.—J. G. Bell, F. P. Bester, H. W. Boreham, E. R. Branch, H. H. Broome, A. L. P. Brown, E. A. Brown, G. H. J. Brown, Robert Bruce, A. R. Buchanan, D. A. Callender, John Cameron, Robert Cameron, H. G. Carlisle, J. G. Carr, H. E. Coghill, Leonard Crossley, E. T. Cyriax, R. M. Dalziel, William Darling, Y. A. Diedzian, F. H. Domuisse, David Ferrier, E. G. Fiench, R. G. Ford, Charles Forsyth, J. J. Galbraith, W. A. Gilbert, A. E. Goldie, T. B. Gornall, J. M. Gray, A. M'W. Green, Bruce Greig, A. H. Griffith, George Haddow, W. D. S. Harrison, H. T. Holland, P. S. Hopkins, C. A. B. Horsford, Alexander Hunter, James Husband, B. S. Hyslop, B. D. King, M.A., H. C. Kenn, A. C. Kirkpatrick, G. R. Laing, J. D. Laing, Thomas Livingstone, James Lucknoff, J. C. M'Conaghey, Edward M'ulloch, P. H. Macdonald, W. R. Macdonald, John M'Gregor, T. J. T. M'Hattie, A. M. M'Intosh, Andrew M'Kaig, G. A. Mackay, W. M. Mackay, Maxwell M'Kelvie, R. C. M'Lachlan, P. A. MacLagan, L. C. MacLagan-Wedderburn, G. C. M'Leary, R. H. Macneill, William Macniven, J. F. Martin, James Mason, M.A., Thomas Meldrum, C. W. F. Melville, F. N. Menzies, G. H. Menzies, F. G. Middleton, J. G. Mitchell, A. H. D. Moore, Alexander Mount, J. H. Munroe, C. F. Neville, T. P. Oates, L. J. L. de Pavillet, John Pender, H. G. P. Raeburn, William Raife, F. E. Robinson, G. B. Robinson, J. R. Robinson, William Rogers, J. M. Ross, Alfred Shearer, T. S. Shepherd, G. F. B. Simpson, A. B. Slater, A. K. Smith-Shand, F. H. Stirling, C. S. Stevenson, W. J. Stuart, W. W. Thom, A. H. Thomas, J. P. Thorne, N. D. Walker, C. H. J. Watson, Arthur Whittome, and A. H. Wood.

The following candidates passed the Second Professional Examination (Old Ordinance) in March and April, 1895:—

D. N. Anderson, Frederick Anderson, R. W. Anthony, Eustace Arkwright, H. S. Ballantyne, B.Sc., J. E. Blackburn, Edwin Bramwell, William Buchanan, L. M. Cairns, T. M. Callender, A. F. Cameron, M.A., H. O. Dougall, Hugh Douglas, Stanley Ducat, A. R. Eates, William Finlay, John Forbes, M.A., B.Sc., Harry Fowler, P. W. Freyer, J. M. de Freitas, D. D. Gold, Norman Gunn, W. F. Harvey, W. J. H. Hislop, J. D. C. Howden, R. K. Howden, Walter Jagger, J. B. Jamieson, C. H. Johnson, T. F. Johnstone, D. T. R. Jones, Henry Jones, R. W. Knox, C. D. Lander, James Lee, J. F. Lindsay, R. E. Loney, A. L. Low, G. C. Low, M.A., J. D. M'Grindle, J. L. Macfarlane, George M'Kellar, A. D. Macpherson, M. W. Manuk, J. E. Martin, Edwin Matthew, Noel Maudsley, F. H. Merry, James Patton, C. H. Phillips, E. C. Porritt, Charles Porter, M. S. Raa, B.Sc., J. A. Rees, John Richards, T. A. Ross, G. B. Serle, J. T. Shirclaw, J. W. Simpson, G. S. Small, H. W. Smith, H. T. J. Thacker, H. M. Traquair, J. R. H. Walker, A. H. Watt, A. E. White, J. H. White, A. R. Wight, W. G. Wight, F. M. Wilcox, A. E. Williams, T. A. Williams, and J. F. Woolie.

Anatomy and Physiology (Old Ordinance).—A. W. G. Clark, James Graham, J. S. Grinsell, Norman Gunn, E. H. Jones, Leslie Kingsford, W. M. Milne, M.A., John Muir, and Oswald Rait.

The following candidates have passed the Second Professional Examination (New Ordinance):—

B. C. R. Aldren, T. R. W. Armour, Thomas Biggam, William Burns, M.A., C. M. Cooper, J. F. Falconer, J. S. Fraser, William Hamilton, Patrick Kinmont, Ian L. MacInnes, John Malcolm, F. W. More, R. G. Riddell, and J. R. Williamson.
Anatomy and Physiology (New Ordinance).—E. P. Baumann, L. W. Davies, W. S. Eaton, George Gatenby, Andrew Gibson, W. E. M'Kechnie, G. W. Miller, J. D. S. Millin, A. H. Pirie, C. M. Robertson, J. D. Slight, M.A., W. M. A. Smith, W. R. Somerset, and J. W. Struthers.

* Passed with distinction.

THE death is announced, at the advanced age of eighty-seven, of Mr. J. Bell Sedgwick, J.P., the old member of the weekly board of governors of the Middlesex Hospital and for many years its vice-chairman. Mr. J. Bell Sedgwick was also for a long period a member of the Metropolitan Asylums Board.

BELGRAVE HOSPITAL FOR CHILDREN.—A special general meeting of the governors of this hospital, to consider the proposal to transfer the hospital to new premises in the Battersea district, will be held at Grosvenor House on Friday, June 14th, at 5 o'clock, by the permission of his Grace the Duke of Westminster, K.G., who has consented to preside.

THE Churchyard of St. Mary's, Woolwich, was opened on May 31st by the Duchess of Fife as a public garden. The work of laying out the ground was undertaken, with the permission of the present rector, by the Metropolitan Gardens Association, the entire cost, over £1200, being defrayed by Mr. Passmore Edwards.

MEDICAL MAGISTRATES.—Mr. John Moir, L.R.C.P., L.R.C.S., L.M. Edin., of Canning-town, has been placed on the Commission of the Peace for the borough of West Ham—Mr. Francis Pafr, L.R.C.P. Lond., M.R.C.S., of Al'ora, and Mr. Joseph Lanterer, M.D. Freiburg, of South Brisbane, have been made Justices of the Peace for the Colony of Queensland.

EAST LONDON HOSPITAL FOR CHILDREN.—The anniversary dinner of the East London Hospital for Children was held on Thursday, May 30th, in Leathersellers' Hall, St. Helen's-place, under the presidency of the Earl of Erroll, who in proposing the toast of "Prosperity to the Hospital" spoke highly of the economy and efficiency of its management. Donations amounting to £2378 were announced.

ST. BARTHOLOMEW'S HOSPITAL.—The committee of the Medical School and of the Amalgamated Clubs of St. Bartholomew's Hospital announce the opening to-morrow (Saturday, June 8th) of the new cricket, lawn-tennis, and football ground at Winchmore Hill, Finsbury Park. The ceremony will be performed by Sir Trevor Lawrence. There will be cricket and lawn-tennis competitions between past and present members of the medical school during the day.

THE Hospital for Sick Children in Great Ormond-street has been enriched by the gift of an isolated building containing a ground-floor ward with three beds for measles, a top storey ward for the same number of scarlet fever cases, together with offices and rooms for the nursing staff. The building has been given by the Misses Lucy and L. nisa Cohen, in memory of their niece, the late Countess of Rosebery.

BETHNAL GREEN GARDENS.—These gardens, which have been purchased from the Government by the London County Council at a cost of £6000, were formally declared open to the public for ever on Monday last, June 3rd. Situated in a densely populated neighbourhood close to the Bethnal Green Museum and covering a space of about nine acres, the gardens, which are beautifully laid out, form a delightful playground for children, while they furnish numerous attractions for the youth and adult.

THE ROYAL SURREY COUNTY HOSPITAL.—At the annual meeting of this institution held in February last it was mentioned that a gentleman had promised a donation of £500 provided that a similar sum could be raised within three months. This offer has been so generously responded to that over £750 has been collected. The cheque has accordingly been forwarded to the hospital for the amount promised, and the donor, Mr. R. C. Garton, of Worplesdon-place, has given permission for the publication of his name.

THE BIRMINGHAM MEDICAL BENEVOLENT SOCIETY.—Mr. Priestley Smith presided at the seventy-fifth annual meeting of this society on Friday, May 31st, when a most satisfactory report was presented. The total sum distributed during the year was £550. Each year shows some slight improvement, and the invested funds now amount to £11,996. The good which the society does in granting relief is performed in a quiet, unostentatious manner and is much appreciated by the recipients. Mr. John Greene was elected president.

PRESENTATION.—On the 29th ult., on the occasion of the distribution at the town hall, Eastbourne, by the mayor of the borough, of the certificates and medallions to the successful members in a recent examination, in connexion with the St. John Ambulance Association, of the borough police force, who had attended the class conducted by Dr. W. G. Willoughby of that town, the mayor presented Dr. Willoughby, on behalf of the members of the

class, as a slight token of esteem and of their appreciation of his valuable services on first aid, with a handsome silver-mounted salad-bowl, fork, and spoon.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Fellows held on Monday, June 3rd, for the election of president, vice-president, secretary, and Council of the College for the ensuing year, the following gentlemen were elected:—President: William Thornley Stoker, F.R.C.S. Vice-President: William Thomson, F.R.C.S. Secretary: Sir Charles A. Cameron, F.R.C.S. Council: Sir George H. Porter, Bart., F.R.C.S.; Archibald H. Jacob, F.R.C.S.; Edward Hallaran Bennett, F.R.C.S.; Henry Gray Croly, F.R.C.S.; Sir Philip Crampton Smyly, F.R.C.S.; Robert Lafayette Swan, F.R.C.S.; Henry Roseborough Swanzy, F.R.C.S.; William Stoker, F.R.C.S.; William Ireland Wheeler, F.R.C.S.; Austin Meldon, F.R.C.S.; William Carte, F.R.C.S.; Sir Charles A. Cameron, F.R.C.S.; Frederick Alcock Nixon, F.R.C.S.; Kendal Franks, F.R.C.S.; Richard D. Purefoy, F.R.C.S.; Charles Bent Ball, F.R.C.S.; Henry Fitzgibbon, F.R.C.S.; Arthur Henry Benson, F.R.C.S.; Francis T. Heuston, F.R.C.S.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill have nearly ready a new work for the use of physicians by Mr. Alfred H. Allen, F.R.C.S., entitled "Chemistry of Urine: a Practical Guide to the Analytical Examination of Diabetic, Albuminous, and Gouty Urine," with illustrations.—The following works are announced by Messrs. Longmans and Co. as nearly ready for publication:—"The Life of Sir Andrew Clark, Bart., M.D., LL.D., F.R.S.," by Malcolm MacColl, M.A., and W. H. Allchin, M.D., F.R.C.P. &c., with an introduction by the Right Hon. W. E. Gladstone, M.P.; "Darwin and after Darwin," by the late George John Romanes, M.A., LL.D., F.R.S.; "Inorganic Chemistry," by G. S. Newth, F.I.C., F.C.S.; "Physics," by W. Watson, B.Sc.; "Ophthalmic Surgery," by William Lang, F.R.C.S., Surgeon to the Royal London Ophthalmic Hospital, &c.; and a "Text-book of Forensic Medicine and Toxicology," by Arthur P. Luff, M.D., B.Sc. Lond., Assistant Physician to and Lecturer on Medical Jurisprudence and Toxicology at St. Mary's Hospital. Dr. Luff's work has been written not only as a text-book for students, but also as a reliable and practical work of reference for general practitioners who may be summoned as witnesses in medico-legal cases.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Whitsuntide Recess.

On Thursday, May 30th, the House of Lords, and on the following day the House of Commons, adjourned for the Whitsuntide recess. The latter will meet again on Monday, June 10th, and the former on Monday of the week following.

Factories and Workshops Bill.

When the Grand Committee on Trade adjourned for its holiday it had not completed the discussion of the clause in the Factories and Workshops Bill dealing with the restriction of overtime. At the last meeting an amendment was moved by Sir Charles Dilke to put women in the same position as young persons, but it was outvoted by 30 votes to 16. Mr. Asquith, while opposing the amendment on behalf of the Government, said that, as a goal to be aimed at, he was entirely in favour of the abolition of overtime for women.

HOUSE OF COMMONS.

THURSDAY, MAY 30TH.

Death Certification.

Mr. Heywood Johnstone asked the Secretary of State for the Home Department if his attention had been called to the death of Charles Rowe, of Charmouth, Dorset, who was brought back to his lodgings at midnight on Dec. 16th, 1894, in an insensible condition and died two days afterwards. Was he aware that Rowe was allowed to remain all night in the passage of the house where he lodged, and no medical man was called in to attend him until late in the afternoon the next day? By whom was Rowe's death certified, and what was stated upon the certificate to have been the cause of death? Was any inquiry made by the police into the circumstances under which Rowe met with the injuries which resulted in his death or any inquiry held? And did he contemplate taking any steps to carry out the recommendations of the Select Committee on Death Certification, and to ensure that every case of sudden, violent, or suspicious death shall be inquired into by a public official?—Mr. Asquith replied that his attention was called to the case in January. Mr. Kerbey,

M.R.O.S., who attended the deceased, gave a certificate that death was due to concussion of the spine and paralysis. Before giving this certificate he informed the coroner of the facts, and was told by him that he might properly give the certificate. Inquiries were made by the police, but they failed to find any ground for supposing the injury to be other than accidental. The coroner, in whose discretion it lay to hold or not to hold an inquest, did not consider it necessary to hold one. The recommendations of the Select Committee were receiving consideration by the Local Government Board, but they could hardly affect a case like this, where the facts came fully before the officer empowered by law to hold a public inquiry. He thought the case was one where an inquiry might properly have been held, but he had no power to give instructions in this matter to the coroner.

The Sewage Farm at Aldershot.

Mr. Campbell-Bannerman, replying to a question on this subject, said it was not known that any case of death could be attributed to the sewage farm at Aldershot, but it was admitted that the farm was not in a satisfactory state. Negotiations with the local authorities were proceeding with a view to a new sewage farm being established at a greater distance from the camp, and meanwhile steps were being taken for the improvement of the present farm.

Increase of Rabies.

Mr. Chaplin asked the President of the Board of Agriculture whether rabies was increasing to such an alarming extent in Great Britain that 339 cases had been reported during the first twenty weeks of 1895, as against 69 cases in 1894, 34 cases in 1893, and 9 cases in 1892 during the first twenty weeks of each of those years respectively.—Mr. Herbert Gardiner replied that it was unfortunately the case that rabies had increased to the extent stated in the question, the increase, however, being practically confined to the counties of Cheshire and Lancashire, and the West Riding. He need scarcely say that the subject was one which was engaging his anxious attention, and he was constantly in communication with the local authorities with a view to secure the efficient enforcement of the muzzling regulations which were now in operation over practically the whole of the dangerous districts. If, in addition, they secured adequate support from public opinion and from the magisterial bench when breaches of the regulations were brought under their notice by the police, there should be no difficulty in effecting an early and substantial improvement of the position as regards this terrible disease.—Mr. Chaplin asked whether the Board of Agriculture were taking any direct action in this matter apart from the local authorities.—Mr. Gardiner said it did not seem necessary for the Board to take direct action because they had induced the local authorities over the whole of the area where the disease existed to put into force the muzzling orders, and the local authorities could see to the enforcement of these orders much better than the Board of Agriculture.

Drainage and Ventilation of the House.

These subjects were raised in the course of the debate on a vote on account, several members complaining of the existing state of things. Mr. Herbert Gladstone, First Commissioner of Works, said the drainage of the House was considered by a committee in 1891, and all the main defects were then made good. He had good authority for saying that the atmosphere in the Chamber itself was as pure as that on the terrace overlooking the river. No sewer air could come into the House because it was carried by shafts in which coke fires were always burning to the top of the Victoria and the Clock Towers.

FRIDAY, MAY 31ST.

Experiments on Living Animals.

Mr. A. C. Morton asked the Home Secretary whether it was possible for the vivisection experiments to be attended by outside and independent persons, so that the public might receive information as to whether there was any cruelty to the animals experimented upon.—Mr. Asquith replied that he had no power to order that the public should be admitted to vivisection experiments, these experiments being carried on in private places. The inspector visited the places under Parliamentary authority, but neither the inspector nor the Home Secretary had any authority to authorise anyone else to go there. The experiments were often of a very delicate nature and could not be carried on properly if the operators were liable to be intruded upon at any moment by representatives of the public. When occasion arose he would be glad to see that the system of inspection was thoroughly efficient, but at present there was no real ground for apprehending any cruelty to the animals.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—6 P.M. Dr. Morgan Dockrell: Bazema.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular in question.

MEDICAL QUESTIONS AND THE "ECHO."

WE have received a letter from "Lennox" of the Echo, referring to a letter from Mr. Lennox Browne which appeared in our issue of May 18th. "Lennox" wants to know if Mr. Browne has the sole prescriptive right to the name Lennox. This seems to us to be rather beside the point. A man is, of course, at liberty to assume any nom-de-plume he chooses; but when it is pointed out to him that this choice annoys someone else it would be courteous to change it. As for prescriptive right, that probably belongs to the dual family of Richmond and certain other Scottish families; and the owners of this ancient name may well exclaim when they see it attached to newspaper medical advice, given, moreover, without the patient being seen, "Ichabod, the glory has departed from Israel."

Laicure.—We agree with our correspondent in most of the points that he makes. But "speaking out bravely"—certainly a compliment in a general sense—may in some circumstances be harmful. We have been exceedingly relieved to see that nearly all the great journals of England have considered that the subject matter of the late scandals made it necessary to abstain from unnecessary comment. With the end of the case has come the end of the chatter.

A FRIVOLOUS CORRESPONDENT suggests that, as the General Medical Council have refused to substitute either of the terms "midwifery nurses" or "nurse midwives" for "midwives," no more appropriate designation could be adopted than that of "foster-mothers."

"AN OPHTHALMOLOGICAL HINT."

To the Editors of THE LANCET.

SIRS.—It seems surprising that no correspondent has drawn attention to the fact that the above is described by Mr. McNamara at page 163 of his work on "Diseases of the Eye," published a quarter of a century ago. It cannot, therefore, be novel to the profession. I have been in the habit of using it for the past twenty years.

I am, Sirs, yours faithfully,

Greenawn Gowra, Naas, June 4th, 1895. JOSEPH SMYTH, M.D.

J. O. E. D.—The name mentioned does not appear upon the current Register of the United Kingdom or in the Medical Directory for 1895. This is not proof positive of absence of qualifications, as duly qualified persons are removed from the Register on failing to notify change of address. There is no reliable or official Register of the members of the medical profession in the United States of America.

Mr. R. H. Baxter.—We never recommend individual practitioners.

THE CASE OF MR. C. B. TOWNSHEND.

The following additional subscriptions have been received or promised, and are hereby gratefully acknowledged:—

Mr. John F. Churchill (Chesham) ...	£1 0 0	Dr. J. H. Wood (Ledbury) ...	£0 10 0

Tasman.—The manner in which the price should be fixed must depend on the security of the income. For some practices two years' purchase may be asked; for others no one could be advised to give one. The larger number of years during which the vendor can show an increasing return for his work the more he has a right to good terms, but we cannot advise upon an individual instance.

M. M. E.—The Society of Apothecaries of London gives a certificate after examination qualifying the successful candidate to act as an assistant in compounding and dispensing medicine. For dates of examination, fees &c. apply to the Hall of the Society, Blackfriars, E.C.

Dr. FitzStevens.—It is certainly not strictly professional, but it is not fair to assume that the paragraph has been furnished by the gentleman himself. He may have had an injudicious friend.

"STRANGE REMEDIES."

To the Editors of THE LANCET.

SIRS,—Your correspondent, Mr. H. Cuthbert, seems to be somewhat surprised at the treatment in his neighbourhood of thrush by hanging a frog head downwards in the patient's mouth, and asks if babes in other localities are subjected to this very disagreeable method. In his interesting book on folk medicine Mr. Black mentions the practice as by no means uncommon in Cheshire as well as in Shropshire, and many of your readers who take an interest in popular customs could not doubt endorse his statement. "It is still by no means uncommon," he says, "for a young frog to be held for a few moments with its head inside the mouth of a sufferer from aphthae or thrush. The frog is supposed to become the recipient of the ailment, which has, indeed, in some districts received the folk-name of 'the frog' from the association. 'I assure you,' said an old Shropshire woman, as she finished her account of the cure, which she had often superintended, 'we used to hear the poor frog whooping and coughing mortal bad for days after; it would have made your heart ache to hear the poor creature coughing as it did about the garden.'"

Under the heading "Humoral Pathology" you mention that a correspondent sends you a cure for jaundice which consists of a drink composed of ale, lemon, saffron, and nitre, followed by a dose of castor-oil on the third day. At the same time the first water after 12 o'clock is to be buried with an ounce of blue stone vitriol. The interest here resides in the burial of the urine, and it is a pity that your correspondent did not give fuller particulars as to circumstances and locality of what is a very widespread practice. Mr. Black, whom it is impossible not to quote in all that refers to folk medicine, says: "In the county of Moray the people were formerly in the habit of paring the nails of the fingers and toes of persons suffering from hectic and consumptive diseases. The parings were put in a rag cut from the patient's clothes, and waved three times round his head with the cry, 'Deas soil.' After this the rag was buried in some unknown place. Among medical men the 'Galenist of much repute' of whom Boyle writes was induced, when other means of cure failed, to boil an egg in his own urine. The egg was afterwards buried in an ant-hill, and as the egg wasted the physicians found his distemper go and his strength to increase. In Staffordshire to cure jaundice a bladder is often filled with the patient's urine and placed near a fire; as the water dries up the jaundice goes."

I am, Sirs, yours truly,

OSCAR JENNINGS.

Paris, June 3rd, 1895.

HOMES FOR THE DYING.

To the Editors of THE LANCET.

SIRS,—An old servant of our family has malignant disease in an advanced stage, seated somewhere at the top of the rectum. He has been advised at more than one general hospital by unimpeachable surgeons that the disease has now made too much progress for an operation. I want to find some place pleasantly situated where he could enjoy the few months he may still have without pain, and yet have proper attendance at hand whenever he has to be medically treated (for a minor operation or injection of morphia). Could you or any of your readers help me by telling me of such a place? Whatever is done should be done at once, as I have gathered from the medical men that six months is the probable limit of the poor man's life. I should like to hear of some place where it is cheerful, and where the patient shall have small indulgences as to hours, &c., good feeding, and good air.

I am, Sirs, yours truly,

June 3rd, 1895.

H. A. B.

ADVERTISING IN SOUTHPORT.

DR. ROBERT ROGERSON, who calls himself "Consulting Physician and Specialist on Diseases of the Chest," has largely distributed in Southport a circular, in which he purports to give references to distinguished men in New York and Scotland. Amongst the latter are the names of Professor Gairdner and Dr. Henry Littlejohn. It would almost be an insult to ask these gentlemen if they had authorised such use of their names.

A. Z.—The obvious arrangement would seem to be as follows. While our correspondent remains the senior partner, his assistant, as junior partner, or salaried subordinate, should draw such share of the returns as represents the work that he does, allowance being made for the influence and prestige of his senior; and when the senior retires, as the junior is not in a position to buy him out, a properly secured charge on the income of the practice should be effected in the senior's interest. What share the junior partner should receive at first, and what share as pension the senior partner should receive later and for how long, are points that can only be settled between the parties; but they should easily be settled with the assistance of a solicitor and good mutual understanding.

Eus would be glad to know of any work dealing with the construction and cost of small isolation hospitals in rural districts or of any society which would advise him on the subject.

Nemo has omitted to enclose his card.

"BILATERAL PARALYSIS OF THE CRICO-ARYTENOIDEI POSTICI."

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to a clerical error in my report of a case of "Bilateral paralysis of the crico-arytеноidei postici," &c. The crico-arytеноidei postici being the dilators or abductors of the glottis and the vocal cords being seen "lying close together," it must be obvious to all who know anything about the larynx that the abductors being paralysed the vocal cords must be adducted. Hence all who read my notes carefully will observe that the word in brackets should have been (adduction) and not abduction. I am sorry the mistake has arisen, but feel confident that those who know will notice that it is but a slip of the pen. I am glad to have this opportunity of adding a few remarks, for since sending my note for publication I have read Dr. Pierre Marie's lecture on *Tuberc Dorsalis*, and find that he states that paralysis of the abductors of the larynx is frequently observed in association with tabes. For my own part, having seen a considerable number of tabes, and never before having met with this association, I think it is rare. Most writers on nervous diseases seem to imply the same.

I am, Sirs, yours faithfully,

FRANCIS HAWKINS.

Reading, June 4th, 1895.

Mr. H. B. Matthew.—We do not know anything of the nostrum or its inventor. The claims made on its behalf are obviously preposterous, and the diet-schedule to accompany the administration of the drug is without meaning. No English physician would treat a case by correspondence unseen and guided only by a record of symptoms detailed to him by the patient or the patient's lay friends.

A Protest.—Our correspondent does not mention precisely of what he complains, and has omitted to enclose exact references to the peccant passages.

THE TREATMENT OF LYMPHADENITIS.

To the Editors of THE LANCET.

SIRS,—A patient of mine has undergone several operations for lymphadenitis. After each it has again returned, but in a different place—the last where it cannot be touched by the knife. I think it might be destroyed by caustics. The patient in every other respect is in excellent health, and not yet fifty years of age. Will any of your subscribers kindly suggest treatment for such a case?

I am, Sirs, yours faithfully,

P. F.

June 5th, 1895.

"INTRA-LARYNGEAL INJECTIONS."

Trachea writes:—"Unfortunately in the inquiry regarding guaiacol and menthol in tuberculous laryngeal disease, signed 'Trachea,' probably from my writing of the word, 'tuberculosis of cords' was printed 'tuberculosis of cows.'"

Detector is thanked for his communication.

THE LANCET

SPECIAL SUPPLEMENT

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND

Published in aid of the Appeal to be made on Sunday, June 16th, 1895.

THE HOSPITALS AND MEDICAL CHARITIES OF LONDON.

THE nature and magnitude of the operations carried on by the hospitals of London have received illustration in our annual supplements of THE LANCET published in support of the Metropolitan Hospital Sunday Fund Collection, of which it has hitherto been our custom to distribute abstracts for the information of those attending places of worship. This year we have so far departed from that custom as to circulate equally widely the whole text of this Supplement, feeling that the immensity of London's charities can only be adequately realised by a study of the actual figures. These figures speak in no uncertain voice of the great demand made on the resources of the Fund, and the need for its careful and discriminating distribution; but they prove also how far it falls short of the real need. It ought to be known that in the metropolis about 2500 hospital beds are unfilled by those for whom they were primarily intended, and that many a noble charity is barely able to exist owing to lack of necessary income. In order that some idea of the actual working of these institutions may be given to those whose help is invoked on Hospital Sunday, we propose to devote this Supplement to a description of the main features of the organisation and resources of a general hospital, which may be said to be at the command of any wayfarer who is unfortunate enough to be struck down by accident in one of London's crowded streets.

It is of course not possible to do justice, by the story of any single case, to the entire organisation which is grouped together under the comprehensive title of the Hospitals and Medical Charities of London, but we shall be content if we can succeed in conveying to the minds of the readers of this Supplement an impression, though vague and inadequate, of the vast and merciful work which is going on daily and hourly in their midst. The details of our story are drawn from the life, although for the sake of continuity in the narrative we may concentrate upon one subject the painful and pleasurable experiences drawn from many individual stories; and the hospital depicted, which to avoid any appearance of invidious selection we leave unnamed, may be taken to be the type which may be found embodied in institutions situated north, south, east, and west in this great metropolis, one of which can always be reached by a short cab ride from any part of the County of London.

A STREET ACCIDENT.

Our patient then is chosen from the ranks of that very numerous and very mixed body who fall victims every day to the street traffic of the city. This is by no means the only considerable source of accident which distinguishes London. On the contrary, as we pointed out in our Hospital

Sunday Supplement for 1891, the street accident forms a comparatively insignificant addition to the sum total of injuries inflicted on the mass of workers in this great metropolis—as, for instance, among the dock labourers and ship hands who fill the East-end hospitals, or the workmen in large breweries and factories, or those engaged in the oft-times perilous duty of house building and repairing, or those who are daily exposed in London's railway termini to risks of injury to life or limb in the operations of shunting and the like.

But the danger of a street accident is ever present to every foot-passenger in the London streets, and can therefore be the better appreciated by the ordinary reader of this article. As a matter of statistics let us quote the following

Return of the Number of Persons taken to Hospital by Police during the Years 1884 to 1893.

Year.	Suffering from accidents.	Suffering from other causes.	Total.
1884	3,192	1,676	4,868
1885	3,126	1,650	4,776
1886	3,289	2,018	5,307
1887	3,512	2,001	5,513
1888	4,033	2,267	6,300
1889	4,096	2,366	6,462
1890	4,381	2,240	6,621
1891	4,735	2,385	7,120
1892	4,694	2,845	7,739
1893	5,248	3,067	8,306
Totals	40,506	22,505	63,011

Take then the following case, which may be paralleled from almost any morning's daily paper:—

"John Smith, aged fifty, was crossing ———-street when, in attempting to dodge an omnibus, he lost his foothold and fell under the vehicle, which passed over him, causing a compound fracture of the bones of his left leg. He was removed by the police to the ———-Hospital."

The newspaper reporter has here in this meagre story skipped the first incident which exemplifies the work of the hospitals. It is not necessary to wait until the patient is brought within the walls of the institution in order to see the work of medical charity in progress. In old days this was otherwise. A requisitioned shutter or the ubiquitous cab would have furnished means of transport from the scene of the accident to the hospital door, with the not infrequent result that the mischief done by the accident was aggravated, and, perhaps, rendered incurable in the course of the journey to the hospital. But now the Hospitals Association has established ambulance stations at suitable points in all

the much-frequented quarters of the town and, under the direction of the police-constable who is quickly on the spot, a convenient and well-appointed stretcher mounted upon wheels is promptly brought from the nearest station. The instruction in ambulance work and "first aid" now so widely given by means of the St. John Ambulance Association has borne much fruit; for many a fracture which with careless handling might have become "compound" has been spared this further injury, and many a limb has thus been saved from amputation. The police, trained to realise this danger that confronts the victim, know how essential it is that the raising of the patient should be done with the utmost possible care, and that he should be placed in such a position on the ambulance that the injured limb is not subjected to any strain or concussion. Once securely lodged on the ambulance, the victim is conveyed through the crowded streets with facility and without the slightest jolting until the door of the hospital is reached. Arrived at the hospital the patient is delivered by the police to

THE HOSPITAL PORTER.

Here we may pause to sketch in a few words the type of man who is to be found at many of these institutions, where he often serves in the same capacity so long as to be thoroughly identified with the hospital. His experiences during this long service must be very wide, and he has to assist in many a pathetic scene. He appears not only as the custodian of the portal, which he jealously guards from intruders, but as the embodiment of the charity which receives every sufferer with open arms. A man of sterling honesty, probably a time-lapsed soldier, and, therefore, well versed in the value of discipline and the importance of deference to authority, he is firm in his exclusion of those who have no business in the place and gentle in his welcome to the sick and maimed. In fine, he is a worthy fellow who may be confidently trusted to carry out his orders and to follow a prescribed routine with the precision of a piece of clockwork. Under his guidance the police officers convey their burden into the casualty receiving room and deposit it upon the couch.

THE CASUALTY DEPARTMENT.

In a large London hospital there is hardly an hour of the day or night in which some unfortunate victim to accident is not being attended to in this department. Injuries of all kinds, from the most trivial of wounds to grave internal contusions, fractured and torn limbs, an abrasion of the scalp or a fracture of the skull, burns and scalds of all degrees—these and many others are admitted in regular sequence, so that the casualty room affords the surgical pupil a large field of experience hardly to be obtained in any other of the departments of the hospital. There are nurses specially told off to assist the dressers in this department, under the supervision of the house surgeon of the week or of a casualty officer, whose duty it is to examine each case in turn and decide whether it be of sufficient gravity to be admitted for treatment into the wards. In the case we are considering there is little time lost in arriving at a decision. The injured man, not yet recovered from the effects of the shock of the accident, is carefully examined, the nature and extent of his injuries taken note of, and directions given for his immediate removal to the accident ward. The porters bring to the side of the couch the ward ambulance, upon which he is carefully lifted, the house surgeon seeing that the injured limb is disturbed as little as possible, and in a few minutes he has been received by the ward sister and placed in the bed which is ready for his occupation. The necessary steps are then taken by the house surgeon and dressers to "set" the fracture; the wound is carefully cleansed and dressed and splints are bound to the limb, so that within the space of an hour or less from the moment of his fateful passage of the street-crossing John Smith is installed in the bed which he must occupy for the next six weeks, and, save for the consequences of a severe shock to the nervous system and the aching pain of his fractured limb, he is in personal comfort and really much more at his ease than the reader inexperienced in such matters could at all suppose.

THE PATIENT'S WIFE OR FRIENDS.

But in the meantime other steps have been taken in a totally different direction. From the letters found in the man's pocket his name and address have been discovered, although he may have been too dazed to give any account of himself. The arrangements which are made for communicating with

patients' friends are simple, but sufficient. If within a reasonable distance of the hospital, the house surgeon despatches a messenger in a cab with directions to bring the wife or other relative back at once, or else a telegram is sent notifying the fact of the accident and the place to which the sufferer has been taken.

So summoned, his wife quickly repairs to the hospital and is conducted at once to the matron's rooms. Here she learns the whole story of the accident and is tenderly and tactfully made aware of the extent and gravity of the injuries suffered by her husband. When the poor woman has recovered from the outburst of grief occasioned by the shock of this intelligence, and, soothed by the tender thoughtfulness of the matron, has regained her self-control, she is permitted to see her husband for a few minutes, and gains comfort from finding how carefully he is being tended.

Now, while this is taking place we may pause to answer a natural question on the reader's part. Who are the various people to whom we have thus been introduced, and whom we have seen fulfilling their various duties with so much skill and tact?

THE HOUSE SURGEON.

The house surgeon is a junior medical officer already possessed of a qualifying degree or diploma, whose studies have been prosecuted at this particular hospital, and whose abilities have marked him out among his fellow students for preferment. He must not only be at hand to deal at any moment with an emergency like the present, but he must also make the round of his particular wards, attending to any patient there who needs his help, and satisfying himself that all is going well. He is, so to speak, the navigating officer during his period of duty, and has qualified for his post not only by obtaining a degree or diploma or both from his examiners, but also by distinguishing himself in the eyes of his instructors by his professional ability and his general fitness for the exercise of his chosen profession.

THE PROBATIONER NURSE.

The probationer nurse is, as her title signifies, a young woman who, having selected nursing as a profession, is undergoing a period of training. Her duties are less responsible than those of the sister or staff nurses, but much of the comfort of the patient depends upon her fitness for her post. She brings his meals, keeps his pillows smoothed, and in a hundred-and-one ways can minister to his comfort by thoughtful acts of tenderness and kindly words. The qualities that go to make up womanliness rather than those which come by training are the qualities which she has the opportunity of displaying; but even in these matters training cannot be dispensed with, for there is a way of performing the simplest service for the sick which cannot be acquired save by instruction and practice.

THE STAFF NURSE.

To the qualities which fit a probationer nurse for her place the staff nurse must add the results of a long and careful training. She must be quick to observe and careful to report all symptoms that indicate the condition and progress of her patient. She must be prepared to undertake the performance of all services which require the eye or hand of a skilled nurse. Her work is not only to look after the comfort of her patient, but also, and even primarily, to promote his recovery, for she must carry on and supplement the surgeon's work, and, under his direction, take the general charge and continuous oversight of the case. To administer medicines, to apportion diet, and to be the patient's *alter ego* in so far as he is incapacitated by injury or by disease is her special province—a province which demands from her some of the very highest qualities of heart and head.

THE WARD SISTER.

The head nurse of the ward is one who has been selected either from among the nurses of this hospital or from another training institution. She must have skill to direct her probationers and the moral power to control her patient. Qualities like these have been her qualifications for her post and have recommended her to the choice of hospital authorities. She directs and controls all the nursing work in the ward, and is held responsible for its efficient performance.

THE MATRON.

The matron is a woman whose position demands still higher qualifications. The whole nursing department is under her hand, and she therefore cannot afford to be deficient in any one of the traits which appertain to an accomplished nurse. If anything is wrong in this branch

of the hospital work she must be qualified to detect it and to set it right. She must therefore have the most complete training for her post. But more than this, she must have the faculty for rule. A hundred times a day her word is law, and it must, therefore, carry weight. But she rules not in a military, but in a domestic, sense, and must be fitted no less to win affection than to command respect. In a word, she must be both a lady and a nurse, and each in an eminent degree.

THE PATIENT.

But it is time that we returned to the patient whom we left in company with his wife. The few minutes' interview is over, the visitor has gone, the house surgeon has paid his evening visit, the night nurse has taken charge, the lights are turned down, and the patient, settled for the night's rest, is holding communion with his thoughts. Slowly the incidents of the day revisit his memory. The departure from home amid the caresses of his children, the fateful walk, and the unlucky crossing of the street, the horrible sensation of falling in front of that advancing omnibus, the rearing of the horses, the frantic grappling at the ground, the stunning

to whom he imparts from his rich store of knowledge those clinical facts which the case in question illustrates. He dwells on the mode in which the injury was inflicted, describes its nature, and explains the method adopted for its treatment, pointing out that the art of the surgeon lies in determining how to so place the limb that the broken fragments of bone are kept in apposition and in a state of absolute rest, so that the "vis medicatrix nature" may be exerted most advantageously. He may have occasion to point out that the bandaging requires readjustment, and he dwells on the injurious effect of careless and too tight application of the bandage. He shows how important it is that the union should be perfect and that the limb should on healing not suffer any "shortening" from want of accurate apposition of the ends of the broken bone, and that the wound will require great attention. The signs of the fracture are indicated and varieties in this form of injury sketched. Then he alludes to the probable course of events, the pitfalls that have to be avoided, and the possible dangers to be encountered, much depending upon the condition of the patient at the time of infliction of the injury.

STATISTICS OF HOSPITAL WORK IN LONDON DURING THE YEAR 1894.

TABLE I.—GENERAL HOSPITALS.*

* We reproduce the term "General Hospitals" as employed by the Council of the Metropolitan Hospital Sunday Fund.

blow, and the slow awakening in this ward with his tearful wife at his side. The meditations are sad, even very sad, but they might have been much worse, and note that even while we are pitying him he has fallen quietly asleep.

With the morning comes a new routine, and the patient finds himself already among friends. He recognises the day nurses of the day before, and feels in a sense at home with them. But there are still new experiences in store for him.

THE SURGEON.

The fractured limb has been set, but the work has yet to be submitted to examination by the surgeon, who will take charge of the case. A careful study of the way in which the fracture has been put up is accordingly made by a surgeon whose high qualifications and large experience have given him rank among the leaders of his profession. He makes any remarks to his juniors that may be necessary and gives directions for the nursing of the patient. On his visit he is accompanied by the house surgeon and dressers and by a number of students,

COMPLICATIONS.

In an ordinary case it might well happen that the course of recovery would from this point be uneventful. But not every case is an ordinary case. Complications arise even out of the simplest conditions, and it is no far-fetched hypothesis to suppose that the patient whose fortunes we are following should develop some acute disorder—such, for example, as pneumonia—in the course of treatment for his fractured limb. This new trouble will demand a fresh line of treatment and lay another department of the hospital under contribution. The rise of temperature will be promptly reported by the nurse, and the house physician will be summoned to diagnose its cause.

THE HOUSE PHYSICIAN.

A very few words will suffice to introduce this official to the reader, for his position corresponds in the medical department precisely to that of the house surgeon in the surgical department, and this latter has been already described. The house physician is soon able to make up his

mind sufficiently to prescribe the general course of treatment and administer remedies.

THE PHYSICIAN.

But the next day the patient is seen not only by the surgeon but also by one of the physicians to the hospital, a man, like his surgical confrère, of the very highest professional standing.

HOSPITAL ADVANTAGES AND THEIR RESULTS.

Thus in all that relates to the treatment of his maladies

being still under treatment. With reference to the number who have died, as we stated in our Supplement of 1890, it must not be supposed that these figures represent so many failures on the part of the hospitals to afford relief. On the contrary, in the great majority of these cases the only form of relief possible was the alleviation of their sufferings during their last moments.

THE TREATMENT.

But once more we must return to our hospital patient, whom we left in the hands of the physician, as well

our casual patient is able to obtain every advantage that skill can confer or wealth procure. The most complete appliances, the most approved ability, and the newest discoveries in medicine and surgery are freely placed at his service, and with what excellent results the large proportion relieved or cured out of the total number of in-patients in 1894 (see summary of tables on page 8) very strikingly shows:—In-patients, 105,014; relieved or cured, 90,361; died, 6493; the remainder

as of the surgeon, to the institution. The details of his treatment, the daily routine of the hospital ward, need not long detain us. The reader will easily understand that where the whole system has been worked out with a view to the successful treatment of disease there is not much which thought and experience can suggest as conducive to the comfort and well-being of the patient that is left undone. As compared with the confusion which

prevails in a small household when a sudden necessity arises for treating a case of sickness, the arrangements of the hospital ward are luxury itself. The cheery faces and manner of the attendants, the comfortable space, the wholesome light, the soothing quiet, the reassuring knowledge that skilful eyes are ever present and skilful hands are instantly at call, these things conspire to make the lot of the hospital patient one of great comparative comfort at the worst, and one which is, to patients whose lot is ordinarily a hard one and subject to severe privation, a season of relief and repose. But whether the stay in hospital be marked for the patient by ease or pain it does not usually last long. A detention of six weeks is about the average duration for such a case as we have here supposed, and the present is a severe case. Taking accidents all round the average period of treatment does not extend beyond three weeks, and although it is not possible to give an equally clear idea of the ordinary duration of a medical case, for the variations are naturally much greater

who, though still confined to bed from physical disability, are yet well enough to take a keen interest in this recreation. Thus in many ways the life in hospital is brightened and made more homelike, and many a patient looks back with pleasure to the time that he spent within its walls. The memory of the pain he suffered there is obliterated by that of the comfort and, indeed, enjoyment of its restful days. A lady visitor tells how a poor cobbler coming from a small dark room in the basement of a dwelling in a court off Oxford-street, and who with some difficulty was persuaded to leave this dreary habitation and exchange it for the bright, airy, and cheerful hospital ward, was so impressed with the difference between the squalor he had left and the comfort he had attained that he confessed how gravely his mind had been prejudiced against hospitals, for in his imagination he had fancied to find them prisons. The realisation of the true facts was almost overpowering. He would lie for hours quietly watching the nurses, who with

in this department, it may be stated as a general result that the average in-patient, surgical and medical taken together, spends about twenty-five days within the hospital walls.

As the patient progresses towards recovery and is allowed to get up or to spend a few hours in the garden (a rare adjunct to a London hospital) or on the terrace, his life is by no means so monotonous as the uninitiated might think. There may be a room set apart where smoking is permitted and reading and games are to be enjoyed. The library department is generally controlled by the chaplain to the hospital, and many of these institutions possess a good assortment of light and wholesome literature furnished by the liberality and thoughtfulness of their supporters.

LADY VISITORS.

It is customary, too, for certain hours to be set apart in the week for the visits of ladies, who undertake the duty of reading aloud to, or conversing with, those patients

gentleness and patience were continually responding to the summons of the sick, and when his turn came to be attended to he would, with enviable courtesy, deprecate the trouble he was causing, and he was once heard to say, half to himself, "Surely Paradise cannot be better than this."

VISITORS TO PATIENTS.

At stated hours twice or thrice a week the patients receive visits from their friends, and whenever occasion calls for it the authorities summon the friends to the bedside. The amount of consideration that is shown in this respect may not be widely enough appreciated; but the more this and similar features of hospital life are known, the more keenly will the public resent the cruel and baseless imputations that are sometimes brought against hospitals.

CHAPLAIN AND OTHER MINISTERS.

One word as to the religious side of hospital life. The

office of chaplain—who in some hospitals is a resident official—is one which demands of its holder many qualities. If he performs his duty conscientiously and sympathetically, if he is a man of tact and discretion as well as full of the charity that he inculcates in others, he may do very much to alleviate the burdens of the sick. But he has need, too, of a wide knowledge of human nature, for he is brought into contact with all sorts and conditions of men and women, some of whom perchance may have no sense of the religious spirit. His ministrations must be unobtrusive and full of kindness. The hospital, however, is unsectarian, and those of the patients who do not belong to the Church of England are allowed to be visited by a duly accredited minister of their own denomination. All, however, can join in the simple services which are held morning and evening in the wards without offending their consciences or disturbing their faith.

THE CONVALESCENT HOME.

But now a new aspect of the case comes into view. After six weeks' treatment a cure has been effected, but the patient is by no means in a condition to resume his ordinary avocation. Even if no permanent disablement should result from his injuries he will be weak from the effects of the accident and the disease. To send him home in this condition would be to impair his chance of perfecting his recovery, and, at the very least, to entail upon him a very serious loss of time by plunging him into surroundings that must needs delay and protract his convalescence. On the other hand, it would be a very bad economy of the means which public charity has placed at the disposal of the hospital authorities to permit the convalescent patient to continue to occupy a bed in the hospital ward. There are cases more pressing than his clamouring for admission, and to retain him would involve the exclusion of one of these. Then, again, the hospital ward is but little adapted to promote the mere recovery of strength. It is organised for a different purpose and cannot well be made to serve the present one. In the case of a patient comparatively well-to-do the solution of the difficulty is simple. He is advised to pay a visit to the country or the seaside, and with a few directions for his management of himself is sent to recruit in sunshine and fresh air. But only a few hospital patients are so situated as to be able to obtain such advantages as these. To the vast majority the loss of wages incidental to the enforced absence from work is a serious drain upon slender resources, and if they are to enjoy the benefits of a convalescent home it must be one provided and supported by public charity. Thus have arisen in connexion with most of the great hospitals smaller affiliated institutions, where the work of cure can be perfected, or Samaritan funds from which the convalescent's own means can be supplemented and the benefits of a pay institution of the kind can be secured to him.

Indeed, the convalescent home has become an indispensable adjunct to the hospital and is one of the features of the extension of well-directed charity which has only been developed within the past thirty years. Amongst the first of these excellent institutions to be founded in connexion with the metropolis were Mrs. Gladstone's Home at Woodford and the All Saints' Convalescent Home at Eastbourne, which for a time were practically alone in supplying the needs of the London hospitals; but now, as the preceding table (No. 3) shows, their number is not only considerable (twenty-three), but many a hospital has, through private munificence and without encroaching upon its own funds, been enabled to establish for itself a home in the country whither patients may be drafted as soon as their condition justifies the removal. Indeed, in not a few cases it is possible to continue the treatment commenced in town under the stimulating and strength-giving influences of pure air and sunshine, with the result that recovery is hastened and complete restoration to health made more permanent. The cost of maintenance of such a home is obviously much less than that of the hospital itself. It requires a much smaller administrative staff, whilst the selection of an appropriate site demands far less outlay than an extension of the hospital building in the heart of London would entail. Nor should it be omitted to mention that by the liberality of the railway companies the cost of removal of convalescents to and from these homes has been made as moderate as possible.

PATIENTS WHO DO NOT RECOVER.

The triumph of hospital work is seen of course in the cases of the patients who are discharged cured. But it must not

be supposed that the death roll affords a measure of its failure. On the contrary, the work of mercy is no less real even although it be less successful in these instances. The subject is not one to which we can venture to do full justice. The horrors of a death chamber from which the stern hand of poverty has shut out the ministrations of the physician and the nurse cannot be here portrayed; but no one who has spent painful hours in the house of death will need to have them explained.

OUT-PATIENT DEPARTMENT.

The treatment of the sick and maimed poor is in no hospital limited to those who gain admission into the wards. As a matter of fact, these form but a relatively small minority of the whole number who are annually the recipients of the charity. The dispensary system—i.e., the obtaining of medical advice and treatment which can be carried out

by the patient at home, or which does not necessitate his confinement to bed—has been engrafted upon that of the hospital proper, until it has become one of the most important branches of the work of the latter. The organisation and arrangements of the out-patient department of a general hospital are matters which have often received much attention and no little criticism. The returns, as given in the Summary of Tables, show the enormous proportions to which this branch of hospital practice has attained, for, whereas in 1890 the total number of visits to this department was 2,429,219, it reached last year to no less than 4,108,039.

Now, when it is remembered that each one of these receives individual attention, the labour thrown upon the medical and surgical staff—labour wholly unremunerated—cannot fail to strike the imagination. In several hospitals it has been found necessary of late years to considerably increase the staff of the out-patient officers, each of whom aims at obtaining eventually his promotion to the charge of in-patients—a promotion which may not come to him until after ten or even twenty years' devoted service. In spite of this there is, as ever, a keen competition for the offices of assistant physician or surgeon; and this fact bears testimony to the high repute which our hospitals bear in the estimation of the medical profession, when a position on the staff involving years of patient work is so keenly sought for.

THE OUT-PATIENTS.

To the patients themselves the attendance demands a considerable sacrifice of time as they await their turn for examination; and here arrangements are generally to be found for supplying them with refreshments at small cost. The charge that the out-patient department is taken advantage of by those who can well afford to pay for medical attendance at their own homes has, we fear, some basis of fact. The various branches included in this department, each with its special officer in charge, comprise those of diseases of the skin, of the eyes, of the ear, of the throat, of the teeth, of diseases peculiar to women, and of diseases of children. To the student the out-patient department is invaluable, for here he meets with examples of the less grave forms of disease which will constitute the bulk of his future practice. During the time allotted to these visits the dispensers are fully and actively engaged preparing and dispensing the drugs prescribed with admirable accuracy and celerity.

THE DISPENSARY.

No visitor desirous of becoming acquainted with the work of a hospital should omit a visit to the dispensary. This department will be found everywhere fully equipped, and its arrangements based on good order and method. It would be impossible for the daily dispensing to be got through within the time at disposal were it not so. The work there goes on almost without interruption, for not only have the out-patient prescriptions to be attended to, but every day there come down from the wards fresh orders which have to be promptly and regularly obeyed. The expenditure upon drugs alone forms no inconsiderable item in the hospital balance-sheet; but there is no such false economy as the stinting either in quality or quantity of the materials supplied. The wishes of the medical staff as to the articles required for efficient treatment are invariably and cheerfully acquiesced in, so that the poorest sufferer may derive the utmost benefit from remedies which would otherwise be far beyond his reach.

THE MATERNITY DEPARTMENT.

There yet remains to be mentioned one sphere of activity in which these great institutions share, that has to do with the care of poor women in their hour of trial, a department which, we venture to think, is regarded by the public with less consideration than it merits. It is an extension of practical charity in a direction which must appeal to the heart of every mother, whilst the manner in which the department is organised and conducted is truly admirable. It is here, probably, that the highest feelings of humanity are experienced amidst the most sordid surroundings, and many a lesson in gentleness and patience under suffering is imperceptibly given to the young man, who learns therein the sanctity of his calling and the magnitude of his future

SUMMARY OF TABLES.

responsibilities. That the poorest woman can command, in time of stress and difficulty, the most skilled attention and service, is something of which our civilisation may well be proud.

GENERAL SURVEY.

We must perforce leave our task half completed. To refer to each of the administrative departments necessary for the smooth working and conduct of a hospital would involve far more space than we have at our disposal; but in order that some idea may be formed of the numbers actually engaged in this charitable work, we have prepared a plan (see previous page) that may be taken as fairly representative of the several sections of hospital management. It is not intended to apply to any existing institution, but to be simply a fair average enumeration of the officers and their subordinates in the governing body, and the three main departments—administration, medical, and nursing—into which the work of a hospital may be divided. When it is considered that all these individuals, from the highest to the lowest, are engaged in the one object—the management of a charitable institution—it is not too much to say that for organisation and discipline a large hospital cannot be surpassed.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

The fact that the machinery of public medical charity, as illustrated by the Metropolitan Hospital Sunday Fund, should have been organised upon so large a scale by voluntary effort will occasion no surprise to an English reader. The service is not only nobler for being voluntary—it is in an important sense more efficient also. It is not a small matter that men of business and great experience of affairs are found willing to devote to the service of the hospitals a large amount of their scanty leisure time; it is

perhaps even more important still that the leaders of the profession in medicine and surgery consider it to be an honour to serve in the cause; and it is of the very greatest consequence to the cause of suffering humanity that a vast body of subscribers and supporters of hospitals are induced to take a personal and purely disinterested concern in their welfare, seeking neither emolument nor dignity for themselves from the connexion, but watching with solicitous care over the fortunes of the institutions in which their interest has become engaged. Thus the Hospital Fund occupies a position of pre-eminent advantage, but its influence is entirely moral, derived from its power of fearless criticism and its application of rules for the just and fair manner in which it apportions its awards. A statement of these awards has been published again in the first column of the tables, which can be compared with the other figures, showing the amount of the work in each hospital and dispensary.

Before the Committee of the Hospital Sunday Fund proceed to their awards they have to be satisfied as to the good and economical management of the institution, the expenses of administration not being disproportionate to that of maintenance.

It would not be too much to say that these rules have passed absolutely without challenge. It will, therefore, we think, be felt that the congregations of the various places of worship of the metropolis could not show in a more practical and unostentatious way their sympathy with hospital work than through the council of the Metropolitan Hospital Sunday Fund. In this way, aided by the eloquent advocacy of their ministers, we may hope that at least £50,000 will be obtained on this Hospital Sunday.

Audited and found correct, this 6th day of November, 1894.

(Signed) HART BROTHERS, TIBBETTS, & Co., Chartered Accountants, Moorgate-street.

* * In the preparation of the voluminous statistics of hospital work which have been here digested and exhibited in collected form (and which have been specially supplied to us in response to our applications, and are quite independent of any returns made to the Hospital Sunday Fund Committee) we have been greatly indebted to a large number of secretaries and other officers of the various medical charities of the metropolis. To them we desire, as on many previous occasions, to return our sincere thanks.—ED. L.

A Clinical Lecture

ON

SYPHILITIC ULCERATION AND SOME
OTHER DISEASES OF THE RECTUM;

WITH REMARKS ON THE TREATMENT OF HÆMORRHOIDS.

*Delivered at St. George's Hospital on Dec. 11th, 1894,*By WARRINGTON HAWARD, F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL.

GENTLEMEN.—As there are at present in the hospital several instructive cases of disease of the rectum, and as diseases of this part of the bowel are of very common occurrence, it may, I think, be useful to take some of these cases as the text of a clinical lecture.

CASE 1.—The first patient to whose disease I will direct your attention is a young woman in Princess Ward, who is the subject of syphilitic ulceration of the rectum. She complains of pain before, during, and after defecation, and of troublesome constipation. These symptoms are of about five months' duration, and were preceded by a dull red rash over the body and some soreness of the throat. Examination of the rectum with the speculum revealed numerous superficial ulcers, which were mostly above the sphincter, but there was one rather deeper ulcer with indurated edges which was immediately within the anus and extended to the junction of the mucous membrane with the skin. The skin round the anus was red and irritable and the anal folds somewhat thickened. There were superficial ulcers on both tonsils and a fading brownish roseolous rash over the trunk. There was slight, firm enlargement of the cervical and inguinal lymphatic glands. The patient was given two grains of grey powder three times a day; an incision was made to the depth of about a quarter of an inch through the base of the anal ulcer, and a suppository of grey oxide of mercury ointment introduced twice a day into the rectum. Under this treatment you will have observed that the ulcers of both rectum and throat have nearly all healed. She is free from pain, and the bowels act without discomfort or difficulty. In this case, as so often happens, we were not able to obtain a distinct history of syphilitic infection; but the rash upon the skin, the ulceration of the throat, and the amygdaloid enlargement of the glands, together with the characters of the rectal ulcers, made the diagnosis of syphilis sufficiently easy and secure. You will observe that this patient complained of pain alike before, during, and after defecation; and this led us to suspect that there was ulceration extending along the rectum to some distance above the anus. The case contrasted well with that of another woman on the opposite side of the ward (Case 2) who complained of pain during and after defecation, but who had no discomfort until the motion began actually to pass, and in whom we found a single oval ulcer at the anus, and nothing above. In Case 2 we could see the edge of the ulcer at the anus, but any attempt to introduce the finger or speculum gave so much pain and excited so much spasm of the sphincter that it was necessary for a proper examination to administer ether. You will often meet with this difficulty when an ulcer is situated just within and at the margin of the anus, where the nerve-supply is very free and the reflex sensibility very acute, whereas even extensive ulceration above the sphincter gives rise to much less pain and spasm. When, therefore, you have to examine a case of painful ulcer at the anus, give a sufficient dose of castor oil to act freely on the bowels, and then let ether be administered; and, the patient being placed in the lithotomy position, an expanding speculum should be introduced and the interior of the rectum exposed to view. As the introduction of an enema tube is often in such cases very painful, it may be undesirable to administer enemata before the examination; a syringe and warm water should, therefore, be at hand to wash out the bowel during anaesthesia, and you should be prepared at the same time to incise the anal ulcer.

The lithotomy position is much the most convenient for examining and operating upon the rectum during anaesthesia, and it can be adopted without any disagreeable exposure even in women, the lower limbs being wrapped in a loose flannel gown and a towel placed over the vulva. An extending

No. 3746.

and self-retaining speculum, made in three skeleton segments, which being separated dilate the rectum without concealing its surface, is a most efficient aid to the examination. With this instrument dilated and fixed in position the rectum can be washed out and a most complete inspection made of the mucous surface. This was the method adopted in the case before us (Case 1) and you were able to see clearly the long oval narrow ulcer with its long axis across the margin of the anus, with its hard, raised edges and its grey base. You saw, besides, that higher up the rectum and within the sphincter were a number of superficial, irregularly-shaped ulcers, of diameters varying from a quarter of an inch to an inch and coated with a whitish film. You will also have noticed that the folds of skin round the anus were thickened and, where they joined the mucous membrane, red and irritable-looking. These were conditions quite characteristic of syphilis and clearly indicating the need of constitutional as well as local treatment. The local treatment consisted in the forcible dilatation of the sphincter so as to produce a condition of temporary paralysis, the free division of the base of the ulcer at the anus and the scraping away of the granulation layer on its surface, and the application of iodoform to all the ulcers. Subsequently an ointment of grey oxide of mercury was used, but this local treatment alone would have been quite insufficient for the healing of the ulcers, which were only one manifestation among others of the general syphilitic infection. You will frequently meet with cases of syphilis in which patients consult you on account of some one prominent symptom, the connexion of which with the preceding infection they do not recognise. For this reason, or perhaps because they wish to conceal it, they do not mention the fact that they have had syphilis, so that it is the more necessary that you should recognise syphilitic symptoms, both by their individual characters and by their concomitants. It must be borne in mind, moreover, that symptoms both of syphilis and of other diseases are liable to considerable modification by the position, the tissue, or the function of the part affected. Thus in the case before us the formation of an ulcer at the margin of the anus gave rise to symptoms which were special to the position of the ulcer rather than to its origin; for the patient had the severe pain at the time of and after defecation, the spasm of the sphincter, and the constipation characteristic of ulcer of the anus. These were the symptoms exhibited in the following case.

CASE 2.—A woman, otherwise healthy, had a simple non-specific ulcer of the anus. It was an example of the vicious circle into which the habitually constipated are apt to enter. Habitual constipation is much more common in women than in men, and women suffer much more frequently than men from ulcer of the anus. This woman had been in the habit of allowing large quantities of hard faeces—which were often expelled with great difficulty—to accumulate in the rectum. For the last few weeks defecation had been accompanied and followed by great pain, and the motions were streaked with blood. The pain and the spasmodic contraction of the anus made defecation increasingly difficult, so that the bowels now only acted at intervals of several days, and then only after aperients. Doubtless the passage of hard faeces had caused a crack or fissure at the anus, and this had been prevented from healing by the repeated irritation to which it was subjected. Then, increasing in area and depth, the ulcer became irritable and painful, and gave rise to reflex spasm when an attempt was made to empty the rectum. Thus, the constipation caused the ulcer, and the ulcer kept up the constipation. For this case all that was needful was an incision through the base of the ulcer, a dressing of iodoform gauze, and the proper regulation of the bowels so as to ensure a daily soft motion.

Let me add to these cases another case of syphilitic disease of the rectum which I have recently seen in private practice, and which illustrates the value of concomitant symptoms in aid of diagnosis.

CASE 3.—A patient aged forty-eight years was brought to me for consultation on account of disease of the rectum, which it was suspected might be malignant. The history told that she had been losing flesh for a year, during which time also she had suffered with increasing frequency of defecation. For about six months she had been passing small quantities of mucus and blood, sometimes without any fecal admixture, and she was distressed by the great irritability of the bowel and the frequent desire to empty it. She had become dyspeptic and depressed, and her complexion had undergone a notable change from that of health to a dull bistre tint.

A A

She was very thin, and an examination of the abdomen revealed four spots of marked tenderness along the course of the colon. In the rectum, above the level of the sphincter, were several irregular, somewhat raised patches of ulceration coated with a grey film; no growth could be seen or felt. The folds of skin around the anus were much indurated. She had pain before defecation, but felt a sense of relief after the bowels had acted. I noticed that she had numerous linear scars on the edges of the lips, and on further inquiry I learned that she had suffered from ulceration of the throat, and from several circular ulcers on the legs, of which I saw the depressed, pigmented, and nearly symmetrical scars. On these facts we based the diagnosis of syphilitic disease of the bowel, and we placed the patient upon the treatment appropriate for that. After our consultation, my friend who had brought the patient reminded me of what I had forgotten—viz., that ten years previously I had treated this patient's husband for a syphilitic stricture of the urethra.

You will notice that in this case there was no ulcer actually at the anus, and therefore there was no pain attending the act of defecation. The pain was felt before the bowels acted, evidently from the irritation of faeces moving over the ulcerated colon and rectum, and when the bowel was emptied a sense of relief ensued. The relation of the pain to the act of defecation will thus often help towards the diagnosis of the situation of the ulcer. The diagnosis of the character of the ulceration will depend partly on the appearance and situation of the ulcers and partly on the concomitant symptoms. Remember that in syphilis ulceration of the rectum is very common, especially in women; and that when in a case of syphilis you see ulceration at one end of the alimentary canal (the throat) it is very probable that there is ulceration at the other end of the alimentary canal (the rectum). Thus you see superficial ulcers and mucous patches in the secondary stage affecting both throat and rectum; somewhat later, when the tonsils are infiltrated and sore; irregular, multiple ulcers with slightly raised bases and grey necrotic surface are found in the rectum; and later still, when gummatous growth and ulceration are occurring in the tonsils, the same condition is frequently met with also in the rectum. This last form of ulceration sometimes simulates malignant disease, and is occasionally almost as destructive; the diagnosis will be aided by the history and other symptoms, and by noting that the syphilitic disease is usually more scattered, and less confined to one part of the bowel, than the malignant. Multiple ulcers of the rectum, especially in young people, are mostly syphilitic or tuberculous. The tuberculous are probably not confined to the rectum; they are more apt to lead to suppuration in the adjacent tissue than the secondary ulcers of syphilis and have not the surrounding growth of those of the tertiary period. Other forms of ulceration to be borne in mind, but which will be distinguished by their concomitants, are the dysenteric, and that rather rare condition, ulcerative colitis. In the investigation, therefore, of cases of ulceration of the rectum, do not neglect to note carefully any symptoms that may help you towards a correct diagnosis of their character, and remember that in none is the ulceration of the bowel to be considered as a mere local disease. Even in so simple a case as the second of those I have brought before you, the due regulation of the bowels was as essential as the local treatment for obtaining a cure, and in the first and third cases, without the recognition of their syphilitic origin, treatment would have been entirely futile. The treatment, then, of syphilitic ulceration of the rectum must be constitutional as well as local. For the first, mercury is almost always necessary, but inasmuch as many of the subjects of this condition are dyspeptic, anæmic, and ill-nourished the administration of mercury should be combined with iron or other tonics and with careful feeding. In the later stages, and in the cases of gummatous ulceration, iodide of potassium should also be given. I think, as a rule, small doses of grey powder, with a little opium if the bowels are irritable, constitute the best way of giving mercury in these cases; but if the digestion is very easily disturbed the drug should be given by inunction or by the calomel bath. When the iodide is given it may be conveniently combined with the ammonio-citrate of iron, and each dose should be given in three or four ounces of water. The bowels must be so regulated as to ensure a soft daily motion without irritation or purgation. For this purpose the admixture of salad oil with the food (or, for instance, with finely minced green vegetables, or with mashed potato, or as a sauce with fish &c.) will often answer well; or the

oil may be taken separately the last thing at night; or a tumblerful of hot water may be taken at night. Aperients are best avoided, but if something more active than olive oil is needed, castor oil or the composed liquorice powder is probably the best. The diet should be nutritious and easily digestible, and all foods leaving an irritating residue (such as currants, figs, and brown bread) carefully excluded. Milk and oily foods are beneficial, and plenty of fluid should be taken. Locally, if the ulceration is severe, and especially in the gummatous form, it is useful to wash out the rectum with a warm solution of permanganate of potash after the action of the bowels, and then to introduce a suppository, which may be of iodoform or of grey oxide of mercury. Iodoform is best at the commencement of the treatment, and if the ulcers are foul or indolent; afterwards the grey oxide of mercury (a drachm to the ounce) is an excellent application. This last I learned from Sir Prescott Hewett. Occasionally, when the ulceration is very extensive and destructive, and especially when it has extended into the bladder, colotomy is necessary. Let me now call your attention to a case of hæmorrhage from the rectum of unusual origin.

CASE 4.—A woman aged thirty was admitted on account of severe hæmorrhage from the bowel. She was extremely anæmic and very weak; the heart was irritable and she suffered from palpitation and dyspepsia. With every action of the bowel she lost a considerable quantity of venous blood, and large masses of venous hæmorrhoids protruded, which were returned with difficulty. All the veins of the lower extremities were enlarged, and many were varicose, especially those of the left leg. Over the left leg there were numerous purpuric spots. Examination of the rectum revealed great dilatation of the whole hæmorrhoidal plexus, and near the anus were numerous large masses of dilated veins which bled freely when touched and which were protruded whenever a motion was passed. The history which the patient gave us was that a year previously she had had a difficult labour, at which instrumental assistance was necessary; that after this she was extremely ill and that the left lower limb became greatly swollen; since then the veins of both legs had become varicose, she had had daily hæmorrhage from the bowel, and she had become increasingly weak from loss of blood. Evidently this woman had had pelvic phlebitis after parturition, with blocking of the iliac veins and consequent obstruction to the middle and inferior hæmorrhoidal veins, upon which followed the venous dilatation and bleeding. An attempt had been made before I saw the patient to ligature some of the more prominent masses of veins; but the bowel was so congested and softened, and bled so freely on being touched, that this was abandoned. The treatment adopted was the long-continued maintenance of rest in the recumbent position with the pelvis well raised, the careful regulation of the bowels, and the application of astringents to the protruded mucous membrane. The long-continued rest gave time for the venous circulation to accommodate itself to fresh routes; for the regulation of the bowels daily small doses of sulphate of soda in hot water were given, which you will find a very useful aperient for producing soft motions and facilitating the portal circulation; the local application was a weak solution of acetate of lead freely applied over the protruded bowel before it was returned. This treatment was continued for nine months, after which she was allowed gradually to resume the upright posture and to walk about. The dilatation of the veins was then greatly diminished. There was no return of hæmorrhage or prolapse, and she went home quite free from discomfort and greatly improved in health.

This leads me to speak of some matters connected with the treatment of hæmorrhoids, three cases of which you have seen recently operated upon, each of which was admitted on account of hæmorrhage from the bowel. This complaint is so common, and you have so many opportunities of learning its treatment, that it may seem hardly worth while to occupy your time in speaking of it in a clinical lecture; but I do so with the object of drawing your attention specially to certain points connected with the subject which I think may be not without interest and use to you. First of all let me remind you that because a person suffers from hæmorrhoids it does not therefore follow that an operation is necessary. I say this because the cases admitted into the hospital are usually such as require operation; but you must remember that these are the severe cases, that they have mostly been subjected to treatment before being sent in for operation.

and that there are a great number of milder cases which are treated outside the hospital, examples of which you will meet with frequently in practice, and which require no operative interference. If, therefore, you judged of the frequency with which operation is necessary in the treatment of hæmorrhoids from the proportion of cases operated upon in hospital practice, you would form a very exaggerated idea of the necessity for operation. Consider for a moment what is meant when we say that a person is suffering from hæmorrhoids. Usually this—that the patient has more or less fulness and dilatation of the veins of the rectum; that this condition may have given rise to the formation of one or more venous tumours which may be protruded and bleed when the bowels act. Sometimes these dilated veins are around the anus and external to the sphincter (external hæmorrhoids), sometimes chiefly within the sphincter (internal hæmorrhoids), and sometimes both at the margin of and within the anus. The skin and mucous membrane over the external and marginal hæmorrhoids are apt to become very much thickened and hardened, and this condition you must take care to distinguish from the hypertrophy and induration of the folds of skin at the margin of the anus often seen as the result of syphilis and also of long-continued vaginal discharge—a condition to which the patient often erroneously gives the name of hæmorrhoids. Internal hæmorrhoids are apt to become pendulous and indurated in proportion to the length of time during which they have existed, and, moreover, often present more or less ulceration upon their surface. There is besides, another variety of internal hæmorrhoids, less common than those already mentioned, which consists of a small sessile vascular growth, chiefly arterial, and which gives rise to very little pain, but very profuse hæmorrhage. Now it will be evident to you that the conditions I have described may be due to a variety of causes, and will require a corresponding variety of treatment, or perhaps no treatment at all; and certainly in many of them no operative interference will be necessary. For instance, a considerable proportion of those who are the subjects of hæmorrhoids are persons whose veins throughout the body are weak and varicose. They have varicose veins in the legs, perhaps also in the arms, and probably also in the spermatic cord. You will remember that the submucous tissue of the rectum is very loose, so as to allow of the varying condition of distension to which this part of the bowel is liable; the veins, therefore, have but little support; they have a long column of blood above them and no valves, and so easily become dilated. Now if such persons avoid constipation and portal congestion and take a reasonable amount of exercise the veins of the rectum, though always somewhat dilated, may give them no more trouble than the veins of their spermatic cord or of their extremities; but if they eat and drink largely, lead a sedentary life, and become constipated the distal veins generally (legs, spermatic cord, and rectum) will become troublesome, and there will be aching pains in the legs, in the testicles, and in the rectum; then, a little bleeding occurring from the bowel, the patient seeks your advice on account of his hæmorrhoids. Such a case requires not an operation, but a reasonable modification of the mode of life, and, if this is taken heed of, may never require anything else. Of course, if these weak-veined people neglect the action of their bowels and otherwise live imprudently, they may easily develop hæmorrhoids of a severity requiring operation; but what I wish to impress upon you is that in the earlier stages of the complaint, such as you will more often meet with in private practice, only such simple measures as I have indicated are required, and that the cases that come into the hospital are mostly the severe and neglected ones. All persons with lax veins should be made to appreciate the immense importance of position in regard to the venous circulation. Many such would avoid all trouble both with the veins of their legs and rectum if they would simply observe the precaution of resting, whenever possible, with the legs raised. This is especially desirable at the end of the day, when it is also usually most practicable; so that the recumbent position in the evening and an occasional dose of Epsom salts would keep many of these patients out of the hands of the surgeon. Another class of persons who are prone to suffer from hæmorrhoids are anæmic young women, who are habitually constipated and who lead inactive lives. Their circulation is feeble, and the presence of hard feces in the rectum is a continual obstacle to the return of the venous blood, and so the veins of the anus become dilated. The mischief is often aggravated by

the repetition of irritating purgatives and by irritating food taken with the idea of combating the constipation, and perhaps by the injudicious administration of alcohol. For such as these the treatment indicated is the careful regulation of diet, exercise, and the digestive apparatus. These girls often have defective teeth and are dyspeptic; the teeth should therefore be attended to, and the food be digestible and unirritating, and taken with a proper amount of fluid. Warm clothing and fresh air are of great importance, and if the patient is too weak for sufficient exercise massage may be used with advantage. Salad oil, hot water, the sulphates of magnesia and of soda, aided by nux vomica—these are appropriate aperients. Such measures as these, carried out carefully and perseveringly, will usually render operative interference needless.

A contrast to this class is met with in the patient who eats and drinks largely, takes but little exercise, and who comes to you with painful hæmorrhoids, a large congested liver, some gouty symptoms, and perhaps a little albumen in the urine. In such persons, especially if gouty, thrombosis is apt to occur in one or more hæmorrhoids, and often with this there is a good deal of inflammation round the blocked vein. These are not good patients for operations of any sort, and probably none will be needed for their hæmorrhoids if they will be persuaded (which they very often will not be) to moderate their diet, leave off alcohol, and take a course of Carlsbad or other saline aperient.

I need hardly remind you that the pregnant uterus and other abdominal tumours may give rise mechanically to temporary enlargement and distension of the hæmorrhoidal veins, which will entirely or to a great extent subside when the cause is removed. Of course, however, repeated pregnancies may lead to persistent hæmorrhoidal dilatation which may require to be removed by operation. Remember also that cirrhosis of the liver and mitral disease are conditions in which occasional bleeding from hæmorrhoids may be salutary. One other point let me remind you of in connexion with the presence of hæmorrhoids—namely, that they may be only part of a much more serious condition. Above the hæmorrhoids may be a malignant growth which, by its interference with the circulation, may give rise to dilatation of the veins below.

But although, as I have endeavoured to impress upon you, there are many cases of hæmorrhoids which need no operation for their cure, yet there will always remain a considerable number which can only be satisfactorily treated by operative measures. Let me conclude my lecture, then, by a few words on the operative treatment of hæmorrhoids. There are a great many different operations for removing them, but the two methods most commonly practised in this hospital are clamping and tying, and in my judgment these two are by far the best operations for ordinary cases. The small, sessile, arterial hæmorrhoid can be successfully and painlessly destroyed by the application of strong nitric acid, but this treatment is not adapted for the other and more common forms of hæmorrhoids. Of the two methods of which I have spoken—the clamp and the ligature—I prefer on the whole the clamp, as it is certainly the less painful; but practically I often combine the two, using the clamp for the removal of the chief masses, and tying any vessels or small surfaces which bleed after the clamp is taken off. If, however, a patient has been greatly weakened by loss of blood it is best to use the ligature only. The results of both methods seem to me to be equally good, but I think the amount of pain after the operation is less and the recovery more rapid when the clamp is used. I find in the hospital records of the last ten years 140 cases of operation for hæmorrhoids; in 85 of these the clamp was used and in 55 the ligature. Among the 140 cases there were three deaths. One of these was certainly in no way due to the operation. The patient, a woman aged thirty-five years, was brought to the hospital in a state of extreme exhaustion and anæmia, having been for six years losing blood from the bowel. A few hæmorrhoids were ligatured, but she died eight days after admission from simple exhaustion. Post mortem nothing was found excepting extreme anæmia. The second death was that of a woman aged eighty-one years, who died from erysipelas following the operation by ligature. No post-mortem examination was obtained. The third death occurred in a patient under my own care. A man aged thirty-four years had suffered for thirteen years from hæmorrhoids and was extremely anæmic. I removed several by the clamp and ligature, and a few days after the operation he developed broncho-pneumonia, from

which he died. The post-mortem examination gave evidence of the broncho-pneumonia and nothing else. There was no peritonitis, no suppuration, and no thrombosis, and the mucous membrane of the bowel was natural. Still, the lung affection followed quickly upon, and was probably in some way connected with, the operation. Considering, however, the number and severity of the cases operated upon it will be evident that the mortality of either of the methods referred to is very small. In conclusion, let me remind you that it is worth while to advise patients who have been operated upon for hemorrhoids so to regulate their bowels, their diet, and their habits of life as to avoid conditions which favour the development of the disease.

THE NATURE OF CERTAIN CATARRHAL AFFECTIONS.¹

By ARTHUR FOXWELL, M.A., M.D. CANTAB.,
F.R.C.P. LOND.,

PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

[DR. FOXWELL first pointed out that the word "catarrh" as used at present simply indicated a morbid histological process common to a great variety of diseases and that it possessed no useful clinical signification. He then referred to views held by him in 1885² to the effect that there was a number of acute febrile affections characterised by catarrhal inflammation which received various names according to the part of the body chiefly involved, but all of which so fundamentally resembled each other that they could but be varying manifestations of the same disease, this disease being of specific constitutional nature, for which he had suggested the name "catarrhal fever." Further reflection made it plain that pyrexia was no invariable concomitant of these affections, so that the substantive term "fever" was somewhat of a misnomer. This led to a discussion of the essential value of the adjective "febrile" in the phrase "specific febrile disorder" and to the conclusion that "absence or presence of pyrexia was no bar to the unity of disease." Dr. Foxwell then continued as follows:]

There thus opens out a very wide group of affections which I would wish to unite under one designation. For the sake of clearness I will ask you to allow me to use a new term for this purpose, and the one I have chosen is "catarrhus." Catarrhus, then, I look upon as a constitutional specific disorder having many varieties of local expression, but I am inclined to think it need not always produce constitutional symptoms, any more than does tubercle in the tuberculous affections of glands or in lupus. It would seem that the toxins of its germ and of the bacillus of tubercle are often incapable of wide diffusion, or else that they cannot induce symptoms unless in a concentrated form, so that for the disease to become constitutional the germs must either exist in several scattered foci or else have an unusually virulent nature. Some localised catarrhs, with frequent subacute recurrences, such as the pharyngeal and bronchial, may thus be cases of catarrhus, the small localised nests of germs undergoing repeated increases in their families whenever any depression in the tissue in which they are dwelling makes it a more suitable culture medium for them. Similarly there may be constant small outbursts of localised tuberculous mischief strictly limited to the apex of one lung. But many—perhaps most—localised catarrhs are due to quite other causes—some entirely independent of any germ and arising from chemical or mechanical irritation; some to the impaired nutrition of the affected membrane remaining after the ravages of a germ other than that of catarrhus—as measles, diphtheria, and whooping-cough; and some again resulting from the impaired nutrition caused by an acute attack of catarrhus itself, though none of its specific germs remain. Thus the track of a tornado may be traced by the devastated land long after the atmosphere has resumed its wonted serenity, just as the damaged mitral valve remains to tell how rheumatic fever once held sway, and the pock-carred

skin witnesses to the disease whose terrors Jenner long since took away. I would include under the specific disorder "catarrhus" the following affections: a variety of acute pneumonia, coryza, tonsillitis, quinsy, glossitis, sore-throat, laryngitis, croup, bronchitis, gastro-intestinal catarrh, meningitis, peritonitis, pleurisy, pericarditis, nephritis, hepatic congestion, vesical catarrh, and some skin affections, as herpes catarrhalis, some erythemas and urticarias.³ I say a variety of these affections, for they can all occur in disorders other than the one under consideration, but then, clinically, their course is different. I never remember to have seen any one of these occurring alone in an attack of catarrhus; and the combinations and permutations of their concurrences in individual attacks are endless.

These combinations are a great argument in favour of etiological unity of the things combined. Who amongst us doubts that the cutaneous and alimentary disturbances of scarlet fever are etiotogically identical? Yet the certainty that exists in this matter is due to their frequent combination in the disease and not because the specific poison has been found in these localities. It is true that often there is a special character in them when they occur in scarlet fever; but, equally so, there is a special character in the respiratory and alimentary disturbances of catarrhus. No one will gainsay that, taking a large number of consecutive cases, the tonsillitis of catarrhus is as characteristic as that of scarlet fever. With regard to frequency of combination, I think the involvement of the respiratory and alimentary systems is quite as frequent as that of the cutaneous and alimentary in scarlet fever. Moreover, this is not all: not only are these conditions frequently combined, but sometimes one and sometimes another element of this combination takes the chief position; and yet—and this is the important point—the general course of the disease is unchanged, though naturally modified in detail in accordance with the special lesion produced. Thus Dr. Ashby⁴ describes the various varieties of pneumonia, his fourth being gastric pneumonia, which he thus defines: "In these cases gastric symptoms are most marked; the attack may begin with vomiting, diarrhoea, coated tongue, fever, and abdominal pain, and it is only after a day or two, when the classical signs of pneumonia appear, that a diagnosis of pneumonia is made." Surely this is no logical position; "gastro-intestinal catarrh with some pneumonia" would be a name much more in accordance with the facts. But as yet it has not been decided to acknowledge a so-called idiopathic form of gastro-intestinal catarrh, so when we come upon it we restlessly search till we find it in the company of some other affection whose right to the term "idiopathic" has already been admitted. Hence, though the pneumonia, even when it is discovered, occupies a very small portion of the disease-picture, yet it is eagerly seized upon as something that is known, and one insists upon calling the whole complaint by its name.

But to my mind the most convincing proof of the unity of all acute catarrhs is in the definiteness of the duration and course of the disease, no matter what part of the body be the chief local sufferer. Take, first, the duration. This varies from three to seven days, depending upon the severity of an attack; a mere coryza may last the seven days, while a pneumonia may end in three; and a peritonitis may be shorter lived than a pleurisy. But whatever the severity or local condition, all varieties of catarrhus have as much right to the designation "one week" as typhoid fever has to its historical "three weeks," and their existence is quite as determinate as that of scarlet fever or of influenza. The course is still more striking in its unity than its duration, and whatever the part affected—

¹ A paper read before the Midland Medical Society on Dec. 5th, 1894.

² Vide (1) The Nature of Acute Pneumonia in Children, Practitioner, July, 1886; (2) Acute Laryngitis in Children, Birmingham Medical Review, February, 1887; (3) Acute Primary Peritonitis, Ibid., July, 1887; and (4) for a full account of the whole subject, Essays in Heart and Lung Disease, published by Griffin and Co., May, 1895.

³ It has been objected to this category of affections that it is so extensive that any disease which includes them all has denotation so largely writ that its connotation must be attenuated almost to a vanishing point. But first, it must be remembered, I do not include all these affections, but only a variety of them all. Bronchitis, e.g., is a name given to the genus of a local morbid process; this genus has many species, some of these species are complete affections, but many are only the various bronchial manifestations of an equal number of constitutional diseases. Secondly, other specific disorders include just as large a number, only the variety is different. To take scarlet fever, Dr. Crooke, in those extremely valuable papers of his on the morbid anatomy of this disease (Birmingham Medical Review, July, August, September, and November, 1886, and June and July, 1887), describes inflammatory affections of the tongue, tonsils, throat, larynx, lungs, intestines, liver, spleen, kidneys, and joints, as well as general acute adenitis; and to these Dr. Line adds (Ibid., March and May, 1887) coryza, otitis, cellulitis, peritonitis, stomatitis, herpes, and the rash; to these, again, I may add pleurisy, meningitis, and bronchitis—a list, it will be seen, quite as formidable as the one I have above detailed.

⁴ Ashby and Wright: Diseases of Children.

whether it be a coryza, the outcrop of a few vesicles, as in herpetic fever, or a severe pneumonia—the onset is always sudden, and in a few hours the disorder is at its height; there it remains for a few days, with little variation; then, in as short a time as it took to arise, it vanishes, leaving traces, it is true, locally, but the constitutional symptoms go completely, leaving only the lassitude of convalescence. Now this rapid vanishment, this crisis, does not strike one so keenly in simple coryza as in pneumonia; but it is there, cut just as clear. Only, the constitutional attack is slight in coryza, and therefore its going does not strike one so vividly; moreover, the local repairs which have to be effected are on the surface and insistent, requiring a blowing of the nose for several days to come, and a cold is not considered to be gone till this local annoyance has gone also. In pneumonia the local repairs take still longer; they are seldom finished in a fortnight from the crisis, but they are neither felt nor seen, and they do not intrude themselves, so that it is convenient to forget their existence. Yet, let the coryza be a severe and prostrating one—an influenza cold, as it is sometimes termed (which, by-the-by, is a bad term, for influenza is an entirely distinct disease)—then the crisis will be as marked as in pneumonia, for the constitutional symptoms were equally severe, and their equally sudden disappearance naturally produces an equal effect upon the senses, especially as in these cases the nasal discharge often goes with almost equal celerity. It will be said that coryza more frequently relapses. I do not think so, if it be treated with equal care. How often is there seen amongst the poor evidence of relapsing pneumonia against which the sufferer has vainly struggled, till at last he has been compelled to take to his bed. But pneumonia cases are usually put to bed at once, and if the same were done for coryza but little of relapses would be seen or heard of. These very relapses are an indication of the unity of catarrhus, for a relapsed coryza is not seldom a bronchial catarrh or a pneumonia itself. Is it not a well-known laic saying that "his death was due to a neglected cold"? But a relapse or exacerbation does not change the specific nature of a disease. Hence in such cases, at least, the added pneumonia and bronchial catarrh can be but fresh symptoms of the original affection.

[It was then argued that in geographical distribution and meteorological conditions bronchial catarrh and pneumonia were practically identical. Further, Hirsch has shown that true croup resulting "from harmful meteorological conditions" generally becomes epidemic under the same influences which set up an unusual prevalence of bronchial catarrh. Alimentary, like respiratory, catarrh is also world-wide, and, as one would expect, the exciting cause is oftener evil food than chill, as is strikingly shown in the recorded outbursts of epidemic catarrhal jaundice. In fact, all these acute catarrhs occur under very similar climatic and meteorological circumstances, and from these points of view, therefore, are probably single in origin. Dr. Foxwell went on to say:]

All these acute catarrhs are probably mutually contagious. Pneumonia and coryza are generally recognised as being capable of reproducing themselves in fresh subjects, and it is also admitted by most of us that, given three men who are equally exposed to, say, chill, the chances are much against all three getting any one form of catarrh; but, whilst one has pneumonia, another will get a head cold, and the third gastric catarrh. Further, it is agreed that, though no doubt a cold may run through a house—that is, is infectious—yet this cold takes very different forms in the different individuals of the household: one has nasal catarrh, another chiefly shivering and general pains, a third a cold on the chest, and a fourth an upset stomach. In this instance, at any rate, all these varieties of catarrh must be etiologically identical, and it is equally evident that this single cause cannot be "chill." On this point Dr. R. Percy Smith wrote to me as follows in 1886: "With regard to the contagion of ordinary catarrh, do you know the interesting fact that at St. Kilda, which is very much isolated from the rest of the world, they have an epidemic of what is called 'stranger's cold' whenever a ship visits the place, and never at any other time, although they are exposed to bad weather and storms!" In the same letter Dr. Smith states that at some schools which he at one time supervised there was an outbreak of various diseases, including facial erysipelas, acute pneumonia, and "thirty to forty cases of herpetic fever," the exciting cause of all these being, he thinks, defective drainage, and he goes on to make this suggestive comment: "I suppose all

one can say is that the 'germs' of these different diseases happened to be knocking about, searching for a proper nidus for development," intending me to conclude, no doubt, that the defective drainage was a depressing cause which afforded this "proper nidus." At Pendlebury, if a nurse in the scarlet fever ward developed a sore-throat, though no other symptom of the fever, we did not hesitate to put it down to the scarlatinal poison; but if a nurse whilst nursing pneumonia patients develops a cold or sore-throat, as she not seldom does—indeed with a frequency, I think, unaccounted for by the logic of chances apart from infection—one does not dream of calling it a pneumonia cold or pneumonia throat. Further, families are often attacked by scarlet fever where some individuals have had nothing but slight sore-throats which would have passed unnoticed at any other time, but which the dread sequela of nephritis has enabled the hitherto hesitating practitioner to diagnose as "scarlatinal throat." Similarly, I have had personal experience of two or three instances—and believe it to be by no means rare—for catarrh to exist in various forms in a household, and for one member to suffer from acute pneumonia; yet it never suggests itself to say that the acute pneumonia, if coming first, produced the other catarrhs, or, if coming later, was caused by one of them. But I feel convinced that if once the contagiousness of catarrh were authoritatively recognised there would speedily be multitudes of examples of such contagion afforded. Another argument in favour of the infectious nature of catarrhus is the frequency with which all other causes fail. The action of chill is greatly overrated. Of pneumonia Dr. Ashby states that in Manchester it is almost equally prevalent at all periods of the year; whilst Dr. Fagge asserts that most writers who have tabulated their cases from this point of view fail to trace chill as a cause in any but a small proportion (59 in 603). And, in speaking of colds, is it not an everyday saying, "I cannot make out how I caught it"? And so long as there is a determination to look only to chill as the cause of coryza, it is likely that this phrase will maintain its reputation.

Of the infectious nature of catarrh of the serous membranes it is harder to speak; it is very rare for catarrh to occur in them alone, and when it does, even if infectious, it would have little chance to spread if limited in its action to a closed sac. But there is the serous catarrh styled "cerebro-spinal meningitis," and Drs. Sturges and Compland suggestively point out the close relationship of this to acute pneumonia. Both conditions are infectious, but are they one and the same? Infection from any disease of the alimentary canal does not often occur except through the stool, and there is good reason to believe that the summer diarrhoea of children is sometimes caused by such direct infection. Hence, though there is by no means direct clinical proof, yet there is much to suggest that all these varieties of catarrh are mutually infectious.

Infection one can scarcely think of nowadays apart from a germ. If, then, all these various affections are to be included under one disease the same germ must occur in them all. The pneumonococcus has been found in all respiratory catarrhs, in meningitis, in pericarditis and pleurisy, in peritonitis, and in nephritis; and cultivations of it have induced a condition resembling acute pneumonia when injected into an animal. I can find no record of its having been searched for in the alimentary tract, but it cannot be doubted that there it would be found as well. Indeed, Flügge, in his work on Micro-organisms, states that injection of cultivations of the "bacillus of pneumonia" into the veins sets up marked gastro-enteritis. It does this, it is true, in company with other germs, but I am not now arguing that the pneumonococcus is the sole cause of gastro-intestinal catarrh, but that one form of this affection is produced by its agency. Its etiological value in peritonitis is much disputed, but Mr. Treves in his *Lectures on Peritonitis* for 1894 on Peritonitis makes it the cause of one of his five subclasses of this disease. He quotes Fraenkel as showing that in 1 out of 20 cases of peritonitis wherein he sought it the pneumonococcus was the only germ found. Also he states that Tavel and Lanz, Weichselbaum, Courtois, Suffit, Scavestre, Nélaton, Gallard, and Monisse have reported cases of peritonitis where the pneumonococcus seems without doubt to have been the cause. In some of these the peritonitis was primary and the sole affection; in others it was secondary (*sic*) to ordinary pneumonia. On the other hand, he states that Netter found the pneumonococcus in the peritoneum in 151 cases of fatal pneumonia,

but that in only two of these was there peritonitis. I do not consider these results of Netter's investigations to be much of an argument against the causative power of the pneumonococcus. If catarrhus be a constitutional disease, then either the germ or its toxins are scattered throughout the body and able to set up mischief in all parts. The peritonium is but little affected by its influence, else peritonitis would be as common as pneumonia. Moreover, the germ of catarrhus must be even more omnipresent than that of tubercle; yet one is no more always being attacked with the disease than one is constantly the subject of tubercle. The bacilli of tubercle have been found in the expectoration of non-tuberculous subjects; similarly the pneumonococcus may be found where no evidence of its evil power is discoverable. Again, Mr. Treves remarks that irritants—e.g., tincture of iodine and liquor ferri perchloridi—produce peritonitis by so affecting the bowel that this allows bacteria to pass through its coats, which, when healthy, it will not do. It may be that the depressing irritation of chill or evil food may similarly allow the passage of the pneumonococcus.

There are several kinds of pneumonia bacilli; they are probably but varieties of the same species, for they are well-nigh identical morphologically as well as in producing pneumonia experimentally; they agree, also, in most of their cultivations, the chief difference being in their growth in gelatine. Of these varieties, those of Friedländer and Fraenkel are the most important. My remarks refer solely to Friedländer's, as I have discovered very few facts concerning the other.

The unity of these catarrhal affections and their specific constitutional nature by no means stand or fall with the capacity of the pneumonococcus to produce them. The germ possessing this power may well be yet to find; and if, on other grounds, there be strong evidence of the existence of such a specific disease as catarrhus this germ lacuna should only be an incentive to fresh germinal research. But, whatever germ be the cause of catarrhus, it must be, like the bacillus of tubercle, very largely dependent upon the suitability of the soil attacked. This suitability, as with tubercle, depends upon two things—viz., inherited predisposition and an exciting cause, this latter being usually of the nature of a sudden depressant.

There are numerous individuals, otherwise robust, who are peculiarly liable to this disease—they "catch cold" on the least occasion. It is true that these colds are usually nasal; but that is merely because frequent bronchial, pulmonary, and intestinal attacks are not consistent with robust health, the individuals suffering from them soon descending into the class of feeble lives and thereupon not suffering so frequently, since they guard themselves more carefully against the exciting cause. But, though the inheritance of catarrhal susceptibility is undoubted, yet the germ of catarrh is pre-eminently, perhaps more so than any other, dependent upon the aid of exciting causes. By far the commonest of these exciting causes is sudden lowering of temperature; so powerful, indeed, is this cause, and so comprehensible in its theory of producing the resulting inflammation, that it is hard to believe that it is not of itself all-sufficient. Years ago I firmly held this creed, and I have given it up with great reluctance. More and more, as time goes on, it is established that in the production of acute disorders three causes are usually brought to bear—viz., predisposition, exciting, and a germ. The exciting cause is the striker of the germ match to the laid fire of predisposition; and, indeed, as with the fire so with the individual, the striking cause is the one which is chiefly amenable to control. Still, though the germ of catarrhus is thus usually so extremely dependent upon external conditions to work evil, this is not always so. And herein lies one of the principal arguments in favour of its existence. Sometimes it does not lie like a dead match with potential vitality only, waiting for the exciting hand to make it kinetic, but unaided it possesses the power to light up disease—to wit, when catarrhal affections become contagious—for a cold not seldom runs through a house, and pneumonia itself occasionally becomes epidemic. It is the existence of these attacks, arising apart from evidence of predisposition or exciting cause, which forms a chief bond of union between catarrhus and other acute specific disorders. Moreover, the indubitably proved greatest frequency of catarrhus at periods of the year and in climates where sudden depressions of temperature and excessive moisture are chiefly concomitant points to these conditions as being peculiarly favourable to the vitality of its germs, and to the supposition that the frequency

of the disease at these times is in great measure due to unusual germinal activity. The occurrence of enterica at special periods is similarly explained.

Catarrhus, then, I would define as an acute specific disorder of a week's duration. The incubation is short, seldom more than forty-eight hours and more often only twenty-four, and during it no special symptoms are discernible. The onset is sudden, the height of the disease being reached in twelve to thirty-six hours; it is usually accompanied by chilliness or a distinct rigor, and vomiting is frequent. There are also headache and muscular pains. The disease continues at its height for from three to six days, and, whatever form its local expression may take, the constitutional symptoms are very constant in duration and cease by crisis. If these should be prolonged there is usually evidence of fresh local injury, and the prolongation is of the nature of a recrudescence or relapse. Pathologically it is essentially an exudation—serous, fibrinous, cellular, or membranous—from one or more of the lining membranes of the body. In severe cases some glandular organs become so seriously affected that acute interstitial inflammation, or even their suppuration, results. Some portion of the respiratory and alimentary tracts are always affected, the naso-pharynx being the commonest of all regions to be attacked. The tonsils and tongue rarely escape, "quinsy" and "glossitis" being the terms used when these regions are most severely involved. Next in frequency to suffer are the bronchi, and after them the pleura, the alveoli of the lungs, and the stomach. Not seldom the intestines are injured as well as the stomach, sometimes so severely as to cause ulceration, when the term "enteritis" is adopted. The pericardium and the meninges of the brain are occasionally the chief foci of the disease, that covering the convexity of the cerebrum—and, curiously, often only one half of it—being the portion of the meninges which usually suffers. The skin lesion is common and consists in a herpetic eruption, usually on the face, especially near the naso-labial junction, but occasionally on other parts of the body. Sometimes this forms the only striking lesion, and the condition is then styled "herpetic fever." A transient erythema, limited to the chest and face, is by no means rare at the onset. The question of the nature of the involvement of the kidney tubules is a very complicated one; that they not seldom suffer is generally admitted, but whether they are often the chief focus of the disease—that is, whether the condition called "catarrhal nephritis" is only one expression of catarrhus—is not so certain, though I believe it to be the case. Peritonitis is without doubt sometimes but one of the local lesions of this disease, as is also a form of acute inflammation of the urinary bladder. The crisis which puts an end to the constitutional symptoms occurs before any attempt at local repair has been attempted. It is evident that, as the parts to be repaired vary so much in character in different attacks, the time occupied by repair will also greatly vary—that is, the duration of convalescence is uncertain. Moreover, it is equally evident that the signs and symptoms arising from the injury done to the parts of the body which have borne the brunt of the attack will vary with the locality, and when the organs affected are important ones may so overshadow the general morbid state that the constitutional nature of the affection may fail to be diagnosed. Pyrexia is usually present, and when present is characteristic. At the onset the temperature rises suddenly to 103° or 104° F. in about twelve hours; with irregular remissions it continues at much the same level till it suddenly drops below normal, when the constitutional symptoms of illness as suddenly cease; thereafter there is usually a day or two of subnormal temperature, followed by a few more days of slight hectic ("post-crisial hectic") whilst the brunt of repair to the damaged organ or organs is being accomplished. The remarkable constancy of this pyrexia, whether it be only the tonsils or a whole lung which are involved, points very strongly to the specific nature of the complaint.

Catarrhus is contagious, though this quality is never strongly marked; the incidence of its attacks nearly always depends upon inheritance and opportunity, as does that of tubercle; but, whereas inheritance plays the more important part with tubercle, with catarrhus opportunity is by far the most powerful. This opportunity is always of the nature of a sudden depressant, and is oftentimes the sudden influence of cold acting in a damp atmosphere. The essential cause is a micro-organism, in all probability the pneumonococcus of Friedländer, but its exact nature is not yet determined. It, like the bacillus of tubercle, is world-wide in distribution

and practically omnipresent where humanity is gathered together, but it only occasionally acquires sufficient virulence to successfully attack an individual in a condition of health. It is not self-protective, in this particular being allied to tubercle and malaria, one attack increasing the predisposition of the sufferer to fall a victim to another. Like other acute specific affections, restoration to apparently perfect health is the rule from a first acute attack, but, as with them, so with catarrhus, the local damage may not be thoroughly repaired, and a debilitated pharynx may be left, just as the ileum in enterica may remain permanently disabled.

It will be perceived that I have for the most part confined myself to generalised statements, and have not attempted to clinch my argument by reference to illustrative cases or analysis of accumulated facts. Time is my apologist, not lack of cases or facts.

Birmingham.

TURBINAL VARIX.

BY WYATT WINGRAVE, M.R.C.S. ENG.,

ASSISTANT SURGEON TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL.

TURBINAL VARIX may be defined as a particular form of hypertrophy which involves the posterior half of the inferior turbinal body, and is characterised by a permanent distension of the venous sinuses.

Morbid anatomy and pathology.—Nasal obstruction with catarrh is usually referred to under the comprehensive term "hypertrophic rhinitis," which embraces nearly all forms of thickening of the mucous membrane. But as there are many varieties of hypertrophic rhinitis, varying in degree from simple swellings to localised accentuations constituting polypi, it will be expedient to classify them according to the predominating morbid changes and in their order of frequency under four chief forms—viz.: (1) vascular, (2) mucoid, (3) lymphoid, and (4) glandular. In the simple and temporary cases each or all of these changes may be found; it is, therefore, somewhat difficult, even microscopically, to decide which variety is represented; but when the disease assumes a chronic or permanent character certain features will predominate and readily determine its nature. It is to a special form of the vascular group that attention is now directed, which, although occurring occasionally in the middle turbinal and even in the septum, will be found to constitute a disease almost peculiar to the inferior turbinal itself. A glance at a normal inferior turbinal will at once throw some light upon this peculiarity. The anterior two-thirds or half appears perfectly smooth, but the posterior portion and lower border present a striking and sharply defined contrast, being rough, swollen, and wrinkled even after soaking in spirit. Serial sectioning equally accentuates the contrast, for whilst the smooth region is characterised for the most part by the presence of glandular and lymphoid structure, the wrinkled part is mainly occupied by cavernous vascular spaces lined by epithelioid plates. These vascular channels—the "Schwellkörper" of Zuckerkandl—are surrounded by several layers of visceral muscle fibres, arranged for the most part in circular and longitudinal directions, whilst some form a series of interlacing bands continuous with obliquely disposed bundles which traverse the intervening connective tissue. Many writers seem to have entirely ignored these muscle fibres; even so high an authority as Greville Macdonald describes the venous sinuses as "consisting of a thin layer of connective tissue apparently not elastic and lined with endothelium."¹ He further states that he failed to find muscular fibres in the trabeculae. This oversight is probably explained by the fact that specimens were examined whose walls were already the seat of morbid changes. These cavernous spaces are apparently supplied by thin venous radicles which, commencing in the hyaloid basement membrane, run a comparatively straight course inwards through the lymphoid and connective tissue to open obliquely in the sinus. In some sections the sinuses are distended with blood, whilst in others they are quite empty and tortuous, a condition which has been described as collapse. This variation doubtless depends upon their condition when removed and the methods of removal. Although their general arrangement does not

conform entirely to that of the corpora cavernosa and corpus spongiosum, the slight histological difference does not justify the view that their nature is not erectile, and that they are never erectile in health or disease (as maintained by Bosworth²); still less so in the light of the remarkable sympathy which these bodies exhibit with sexual and developmental phenomena. Attention is specially directed to these muscular fibres, because in their morbid conditions is to be found an interpretation of the pathology of one form of turbinal disease. Owing to the courtesy of my colleague, Mr. Carmalt Jones, an abundant supply of material has afforded me an opportunity of tracing the varying degrees of degeneration which this erectile tissue undergoes, and the conditions were so constant in their appearance as to justify the view of a more

FIG. 1.

Portions of inferior turbinals exhibiting different degrees of varix (natural size).

than merely coincidental connexion. The peculiar villous or brain-like macroscopic appearance of the surface was seen microscopically to correspond with a cystic invagination of the surface epithelium, covering distended loops of vessels with very thin walls, embedded in mucoid tissue—that is, connective tissue in which the matrix mucin was in excess of the fibrous reticulum and cells. The muscular walls of the vascular sinuses presented well-marked atrophy and degeneration, varying from simple thinning to complete disappearance, owing to the fibres apparently sharing in the surrounding mucoid changes. (Figs. 2 and 3.) In places the intervening mucoid tissue simply formed their boundaries, whilst in other parts the walls seemed to have undergone fibrotic changes. This condition is therefore not a mere hypertrophy of the structures, but consists of a true degeneration and infiltration of the walls of these vascular spaces, a morbid process

¹ Diseases of the Nose, pp. 14-16.

² Treatise on Diseases of the Nose and Throat, vol. i.

which is responsible for the disease, for the walls gradually losing their power of active recoil, the vessels by degrees become more and more distended and a permanent enlargement ensues which is in fact a varix.

Etiology.—The conditions which favour the development of this disease are so gradual and progressive in their influence that it is somewhat difficult to discriminate between the direct or immediate and the indirect or remote causes. Whilst admitting that a persistent exaggeration of the functions of the turbinal bodies may constitute a predisposing factor, it is difficult to believe—particularly in the light of the histological changes—that simple hypernutrition could be followed by any change other than hypertrophy of the vessel walls. But, given a tendency to mucoid degeneration or diathesis, due probably to some tropho-neurotic influences (local or general), excessive erectile activity of the parts must play an important rôle. In some instances the presence of an excess of small-cell tissue is strongly suggestive of an inflammatory process preceding the mucoid changes, and from the frequency of this disease among the London East-end aliens it is highly probable that various unhygienic conditions of living—such as prolonged exposure to very dry or very moist atmospheres more or less charged with impurities, particulate and gaseous—must exercise marked predisposing influences by keeping up constant irritation. That there is a hereditary tendency to hypertrophy of the mucous membranes of the nostrils there can be but little doubt, and this is often associated with a highly emotional temperament.

FIG. 2.

Section of the posterior end of an inferior turbinal with dilated vascular spaces (low power).

With regard to sex, males appear to be more frequently affected than females in the proportion of about five to three. Although considerable enlargement of the turbinals may be seen in early youth, turbinal varix is extremely rare before puberty, but after this period it may appear at any age. All conditions in which the venous flow is interfered with, such as intemperance with its attendant hepatic troubles, gout, pulmonary and cardiac diseases, with sedentary habits, will naturally be predisposing factors, for in most of the well-marked cases varix was present either in the tongue, legs, arms, or spermatic cords. The presence of enlarged faucial and pharyngeal tonsils will doubtless predispose by favouring nasal catarrh and by mechanically interfering with the venous flow; but the coincidence of adenoids is by no means frequent, which is not surprising considering the age. Excessive use of the nasal douche must not be overlooked; but perhaps by far the most likely exciting or direct cause will be found in the different forms of nasal stenosis, such as morbid states of the septum, collapse of the alæ, and general thickenings of the nasal mucous membrane, which not only favour catarrh and the accumulation of its products, but by obstructing nasal breathing cause exhaustion or rarefaction of the air posteriorly and consequent expansion of the venous sinuses, whose muscular walls may be already undergoing mucoid changes. Thus, nasal obstruction, combined with a predisposition to

varix and mucoid degeneration, may be considered as mainly responsible for this disease.

Symptoms.—Collectively, the symptoms are those of nasal stenosis, such as mouth breathing and its inevitable sequelæ, parosmia, anosmia, and middle-ear troubles, especially distressing tinnitus. But there are several which, from their constancy and persistence, possess a special significance—viz., a shiny, sanguinolent discharge, generally expectorated in large quantities on waking and not euphemistically described by patients as "blood and corruption," occasional attacks of severe epistaxis, and either painful tenesmus of the faucial and pharyngeal muscles or paresis of the palate. These constitute a group of phenomena interesting in their striking resemblance to those of hæmorrhoids elsewhere and are in themselves almost pathognomonic of the disease.

Diagnosis.—Owing to the swollen state of the nasal mucous membrane a view of the hinder half of the inferior turbinal by anterior rhinoscopy is generally difficult, whilst a satisfactory posterior rhinoscopic image is prevented by the frequent faucial tenesmus; but a thorough cleansing, followed by the application of cocaine, will greatly facilitate an inspection in either direction. If seen from the front a dull red or purple mass may be found at a varying depth, on one or both sides, which does not shrink much under cocaine, but readily yields to the probe and does not change its position on forcible respiration, features which will enable an experienced observer to exclude ordinary catarrhal tumefaction and simple polypus. Still, it not infrequently

FIG. 3.

Section of the posterior end of an inferior turbinal exhibiting degeneration of the muscular fibres of a vascular space (one-sixth of an inch).

happens that the actual conditions can only be appreciated by a successful posterior rhinoscopy, which will reveal a red or purple brain-like mass projecting into the post-nasal space on one or both sides. In all instances, however, digital examination will at once afford by far the most reliable and available evidence. A soft, resilient, yet sharply circumscribed symmetrical mass will be felt on each side of the nasal septum, free all round except at its attachment to the inferior turbinal bone. This evidence, together with the existence of varix elsewhere, faucial tenesmus or paresis, blood-stained discharge, and the general history, will sufficiently indicate the nature of the lesion and enable a satisfactory diagnosis to be made from other forms of hypertrophic rhinitis, from polypi, and from other neoplasms, innocent and malignant.

Prognosis.—Should the foregoing description and interpretation of the morbid anatomy be correct, it is obvious that the possibility of a spontaneous cure is most remote, for the tendency will be towards a gradual but certain increase in the size of the varix. The clinical history of these cases amply confirms this view, for although the severity of the symptoms may vary, or even sometimes apparently remain stationary under palliative treatment, the almost inevitable result is that radical measures are demanded sooner or later. But it is quite possible that milder forms may, by judicious treatment, be arrested in the early stage. Should treatment,

however, be delayed for several years, the enlargement assumes such proportions that, on surgical attention becoming urgent by reason of the profuse bleeding and the stenosis, a diagnosis of angiomyxoma, papilloma, or some other form of nasal growth is often made.² General thrombosis of the mass is a somewhat rare termination.

Treatment.—The treatment will be palliative and radical. Palliative remedies, such as alkaline and astringent douches with general depletion, can only afford temporary relief, and must only be considered as preliminaries to a more thorough and permanent treatment. The radical measures will be directed first towards the removal of obstructions in the anterior regions of the nostrils, and afterwards to the treatment of the varix itself. Should any mucous polypi be present they must be removed, and any localised hypertrophy of the anterior end of the turbinal bodies or septum should be reduced by the galvano-cautery, chromic acid, or snare. Activity of collapsed also may be restored by massage and wearing short pieces of rubber tubing or nasal rings. The portal system should be depleted by a mild course of mercury and chalk or saline aperients. Direct treatment will be determined by the size and duration of the varix and its response to the action of cocaine, for should it be small and of probably only a few years' duration it may more readily contract. This degree of hypertrophy will most likely yield to the galvano-cautery, which should be applied either by plunging a fine point well into the substance of the cavernous tissue or by deeply scoring it with the fine edge of a flat point. Fused chromic acid if applied *secundum artem* is often very satisfactory. A slough generally separates about the fifth day, and cicatricial fibrosis with strangulation of the enlarged vascular spaces soon follows. Both nostrils should on no account be cauterised at the same sitting. When the swelling, however, is very large, and does not shrink under cocaine, caustics are absolutely useless, and complete removal is necessary. This may be affected either by means of a snare or a cutting instrument. Of the former the cold snare or *torasseur* is preferable to the galvanic, for it will, if necessary, cut through a portion of the bone, and if gradually tightened will not be followed by hæmorrhage, nor will it cause any subsequent sloughing, as is often the case with the galvanic loop. If only soft tissues are to be removed Krause's snare succeeds admirably, but either Jarvis's or Wilkin's is preferable when it is decided to include the bone. As a rule, there is no difficulty in engaging the swelling if the wire is directed by a finger in the post-nasal space. But by far the most satisfactory results, as far as complete enucleation is concerned, are to be obtained by the ring- or draw-knife, as introduced by Spencer Watson in 1888, and greatly improved by Carmalt Jones. (Fig. 4.) It has the great advantages of being effective,

FIG. 4.

Carmalt Jones's improved ring-knife.

rapid, safe, and painless, only ordinary dexterity being demanded by the operator. The operation is conducted as follows. The patient is seated on a chair in the usual position for nasal inspection, the head being steadied by an assistant. After freely cleansing the nostrils with an antiseptic douche and applying cocaine (a mouth prop being introduced at discretion) the knife is introduced into the nostril with its cutting side directed towards the diseased turbinal; the guarded index-finger of the disengaged hand is passed by the mouth into the post-nasal space and directs the ring into its proper position around the varix. The shaft is then directed slightly towards the opposite side of the face and sharply but firmly withdrawn in that direction,

cutting its way through the turbinal body, which either escapes at the same moment or is subsequently removed by forceps should it not be dislodged by the patient blowing down the nostrils. By keeping the axis of the instrument across the median line and by varying the angle it is possible to remove only the particular part which is diseased, so that the anterior and healthy portion is left intact and the possibility of laying open the maxillary sinus is reduced to a minimum. The opposite side is then treated in the same way. Bleeding is generally profuse for a few minutes, but is easily controlled by dry tannin and lint plugs. These should be followed by plugs of boracic lint, firmly packed and left in for twelve or twenty-four hours, absolute rest in the semi-recumbent position being insisted upon. The plugs are removed at discretion on the second day, when the nostrils should be gently cleansed with Dobell's solution. Owing to the rapidity and almost painlessness of the operation the major æsthetics are neither necessary nor are they expedient, cocaine proving quite sufficient; still, in the case of very nervous patients nitrous oxide gas may be exhibited with advantage, for the operation is easily completed during its influence. The use of the ring-knife has one advantage in particular over the snare in that it removes all the diseased tissue at once, for it often happens that the varix extends for some distance along the inferior border of the turbinal and is very difficult to include in the snare. Two important complications are to be guarded against—viz., septic changes and secondary hæmorrhage. The first of these need not be feared if ordinary antiseptic precautions are taken, especially with regard to local cleansing before and after the operation, for, beyond a slight elevation of temperature, in upwards of 200 cases of turbinotomy at the Central London Throat and Ear Hospital there is no record of any trouble of this kind, which is somewhat remarkable, considering the dirty domestic surroundings of many of the out-patients. With regard to secondary hæmorrhage, this may occur as late as fourteen days after operating, and, as it is generally occasioned by the patient's disregard of the instructions as to absolute rest and removal of the dressings, whenever practicable he should remain in bed for three or four days, and under observation for at least a fortnight. Although sometimes the bleeding is alarming, ordinary measures are quite sufficient to stop the flow.

Results.—The swollen anterior end of the inferior turbinal soon shrinks, and free breathing is quickly established, with a corresponding amelioration of the symptoms. But are the results always so satisfactory? Certain undesirable sequelæ have been advanced as likely to follow turbinotomy—viz., (1) increase in size of the nasal cavities, anæmia, general atrophy of the mucous membranes of the nose, naso-pharynx, and larynx, with the usual troubles attendant upon imperfect filtration of the atmosphere; (2) opening up of the maxillary sinns and subsequent suppuration; and (3) falling-in of the nostrils and deformity. Having personally investigated the subsequent history of over 200 cases, some of which were operated upon as far back as three years, none of these evils were found to have occurred. That atrophy of the mucous membranes may follow it would be unreasonable to deny, but it is only fair to assume that it occurred in patients who were subject to atrophic rhinitis, which was not recognised in its early stage and for which milder measures would have sufficed. Permanent deformity due to collapse of the nostrils I firmly believe to be a phantom, for it not infrequently happens that, instead of an unnaturally roomy nostril, a distinct reproduction of the mucous membrane follows in the form of a ridge extending backwards from the anterior vestige of the turbinal crest which remained, presenting the appearance of a normal inferior turbinal. This was so remarkably shown in a case treated by Mr. Carmalt Jones that he removed a portion of the new turbinal two years after turbinotomy for microscopic examination. I found that it consisted of normal mucous membrane complete in its details. In two instances this turbinal spur was sufficiently prominent to require reduction by cautery. It is quite possible that the hiatus maxillaris may be enlarged, but that does not necessarily entail any serious results; at all events, I am not aware of its having occurred in the practice of the hospital to which I am attached. It is easily avoided by confining the portion removed to the region which is diseased, a restriction which is not always observed. In conclusion, it is not surprising that there should be some diversity of opinion regarding the pathology of a structure whose normal histology is the subject of so much dispute. It was, therefore, with the hope of obtaining some further evidence that I

² Sandford: Transactions of the British Laryngological and Rhinological Association, vol. III., p. 13. Luc.: Archives de Laryngologie, December, 1890. Spencer Watson: Journal of Laryngology, July, 1893.

availed myself of the plentiful supply of material at my disposal. This investigation has, I venture to advance, established not only that visceral muscle fibres do exist in the walls of the venous sinuses, but that their morbid changes are responsible for the form of vascular hypertrophy which I have ventured to call "turbinal varix."

Tavilton-street, Gordon-square, W.C.

CASES OF LIVER AND GALL-DUCT SURGERY.¹

By JOHN D. MALCOLM, M.B., C.M., F.R.C.S. EDIN.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

In this paper I propose to relate in detail the histories of all the cases of disease of the liver or of the gall-ducts on which I have operated. The cases consist of three in which exploratory incisions were made, two operated on for hydatids, and three in which gall-stones were extracted. The three patients on whom I performed exploratory operations died from the progress of diseases which it was impossible to cure by surgical means, but the operations did not, directly or indirectly, bring about or even hasten the fatal results. The other patients are alive now.

CASE 1. *Exploration; nature of disease not discovered.*—The first of the exploratory operations was performed on a woman forty-five years of age, whose family history gave no assistance in diagnosis. She said that a soft tumour had been taken out of her lower jaw eighteen years before I saw her, but I have not been able to get any account of this operation. She had suffered from bilious attacks for ten years at almost every menstrual period; the severity of these attacks had, however, been much less for two or three years. A swelling in the abdomen was first noticed in February, 1891, and it had grown considerably before she was admitted to the Samaritan Free Hospital in the following May. At that time there was a slight yellow discolouration of the skin and conjunctivæ. In the right loin there was a solid, smooth tumour, with a rounded outline, fairly movable and not tender, extending from the costal margin to close to the pubes and beyond the edge of the rectus muscle on the left side. It stood out prominently from the rest of the abdominal surface in front. The growth was believed to be connected with the liver, but no definite diagnosis was made. As it was growing rapidly an exploratory operation was performed on June 16th. The tumour was found to consist of a rounded swelling of the upper part of the liver, the gland being so displaced and twisted that the abnormal enlargement presented anteriorly. There was no hardness and no irregularity of outline in the growth, and, except for the alteration of shape, the surface of the organ appeared to be quite healthy. By passing the finger below the liver I found that the anterior border of the gland was of normal shape, but was directed downwards and slightly backwards, so that it had not been palpable before the abdomen was opened. It seemed as if the whole liver had been displaced downwards and twisted on its axis by something growing in or behind the upper and posterior part of it. I plunged a trocar and cannula deeply into the thickest part of the gland. The instrument appeared to pass through soft tissues of uniform consistence, and when the trocar was withdrawn nothing but blood escaped. The hæmorrhage was very free, spouting a foot and a half to two feet into the air, and continuing after the cannula was withdrawn, so that I feared it might go on to a dangerous extent. It did not seem as if anything more could be done in the way of curing the patient, and I therefore applied sponge-pressure to the puncture opening and inserted the sutures in the external wound. By the time these were in place the hæmorrhage had almost ceased, and I closed the wound without any anxiety on this point. There was no trouble during convalescence. The patient went home on July 6th, the swelling continued to enlarge, and she died on Oct. 8th of the same year. There was no post-mortem examination and I did not see the patient after she went home, but, as far as I can gather, death was due to asthenia, and no definite diagnosis was made. The operation in this case was most unsatisfactory in that no benefit resulted, and I did not even find out the

exact nature of the disease. The fact that there was no post-mortem examination leaves the case permanently an obscure one, but I think some light may be thrown on the matter by the following history. On Nov. 30th, 1894, I saw a woman thirty-eight years of age in consultation with Dr. Malcolm Mackintosh, of Clapham-common. She was suffering from abdominal distension and pain, sickness, and frequent profuse evacuations of the bowels, the stools consisting almost entirely of watery mucus. There was some slight fever, but no jaundice and no renal or heart disease. The patient had borne three children, the third being eleven months old. The symptoms, which had developed very rapidly, suggested the possibility of some pelvic mischief causing irritation of the rectum, but after a careful examination I could find no explanation of the condition of the patient in her pelvis. The liver was very much enlarged, the anterior border of the right lobe being quite free, soft, and natural to palpation, but displaced downwards nearly as low as the anterior superior iliac spines. Owing to the distension I could not define the left lobe by palpation, but percussion showed that it also was enlarged. No definite diagnosis was made, but I thought the mischief was due to something in or behind the liver, which was pushing its lower border, and especially the right lobe, downwards. Treatment was directed to relieving the distension and supporting the strength of the patient, and sometimes the flatulence dispersed, the abdomen becoming flat, but a tendency to tympanitis continued to the last. The progress of the case continued to be very rapid, and about a week after I had seen the patient Dr. Mackintosh discovered distinct nodules on the surface of the left lobe of the liver and was able to make an exact diagnosis. The patient died a month after my visit, on Jan. 1st, 1895. After death Dr. Mackintosh obtained permission to examine the body, and found a moderately hard carcinoma, which seemed to have originated on the under surface of the liver in the region of the portal fissure. There were cancerous nodules scattered through the whole organ; but these were more numerous in the left lobe, fewer and apparently of more recent development on the right side. Dr. Mackintosh attributed the profuse discharge of mucus from the bowel to congestion of the intestine from pressure on the portal vein, a view with which I fully agree. No cancer was found in any other part of the body. There is a considerable resemblance clinically between this case and that of the patient whose abdomen I explored, as above related; and if we accept the view that pressure on the portal vein was the cause of the exhausting discharge in Dr. Mackintosh's case it is obvious that a tumour more deeply placed in the liver substance might have led to a more prolonged illness, and might have induced death without yielding any signs by which a positive diagnosis could be made during the life of the patient, as in the first case.

CASE 2. *Exploration; malignant disease of the liver.*—My second exploratory operation was performed on a patient about sixty years of age, who was under the care of Mr. Evans of Clapham-common. She had suffered from pain in the neighbourhood of the gall-bladder with liver symptoms of many years' duration, and Dr. George Harley had seen her and had advised that an exploratory operation should be performed. When I saw the patient on Jan. 22nd, 1892, she was emaciated and intensely jaundiced. The liver edge was somewhat lower than it normally should have been, and immediately below it, in the position of the fundus of the gall-bladder, there were two very hard substances, about the size of hazel-nuts, which lay close to the abdominal wall and exhibited some mobility on each other. They felt very like two calculi in the gall-bladder. I made an incision through the abdominal wall just large enough to admit my finger, and on examining the parts I found that the two hard substances were growths standing out from the lower surface of the liver close to its anterior border, and that there were many nodules scattered over this surface as far as my finger could reach. The upper surface showed no irregularity of outline. The gall-bladder was not distended. As the disease was evidently malignant I at once sewed up the wound. The operation gave rise to little disturbance and the incision healed without trouble, but the patient became gradually weaker and died of asthenia on March 5th, six weeks and a day after the operation. When I had examined the parts with my finger inside the abdomen in this case I at once observed that calculi in a gall-bladder could not have remained in position close behind the abdominal wall without being fixed in some way, and there had been no

¹ A paper read before the Medical Society of London, Feb. 25th, 1895.

evidence of distension of the gall-bladder or of any condition that would place and firmly hold two calculi fixed in the fundus.

CASE 3 Exploration; malignant disease of the pancreas and duodenum.—A third case on which I operated may be regarded as one of exploration of the gall-ducts. The patient had intense jaundice and a large ovarian tumour which prevented any satisfactory examination of the hepatic region. I removed an apparently simple ovarian cystoma, and found that the patient had also a malignant growth of the pancreas. There was no trouble from the operation, but the patient died five weeks after from asthenia, and at the necropsy it was found that the pancreatic tumour involved the descending portion of the duodenum, which was converted into a tube of cancerous tissue so thin in parts that it appeared to be just on the point of bursting. (The case is fully reported in THE LANCET of Sept. 8th, 1894.)

CASE 4. Three operations for hydatids of liver and of sub-peritoneal connective tissue.—My first case of hydatids was sent to the Samaritan Free Hospital in November, 1890, by Mr. Starling of Charlton. The patient, who was then thirty-three years of age, complained of having "lumps" in the upper part of her abdomen, and said that she had suffered from crampy pains in the bowels from time to time for sixteen years. These pains had become more frequent and more severe, and she had first noticed the tumours when she was carrying a child that was born two years before I saw her; but two years before that time Mr. Power of East India-road, who attended her in her first confinement, told her that she had a tumour, for which he recommended her to seek treatment in some hospital. On examination I found an oval mass at the back of the abdominal cavity a little below the position of the left kidney, somewhat movable, but too small and deeply placed to allow of an opinion being formed as to the presence or absence of fluctuation in it. A little to the right of the normal position of the gall-bladder there was another tumour, rather larger than the first, attached to the lower surface of the liver and distinctly fluctuating. After the patient had been under observation for some weeks a third tumour was discovered a little to the left of the middle line and fixed to the lower edge of the liver by a band-like attachment about half an inch long. All these swellings rapidly increased in size, and in February, 1891, the left one was rather larger than a healthy kidney; the right was nearly round and measured four inches in diameter. On percussion it exhibited the peculiar thrill of a hydatid cyst. The more central growth measured about two inches across. The liver dulness began at the level of the nipple above. Immediately below this point an absolutely dull note was elicited for nine inches, as far as the lower border of the largest swelling, the patient being rather a small woman. To the right and left of this swelling the liver dulness was lower than normal, but the note was resonant over the two smaller tumours. The whole abdomen was slightly distended. At the back the liver dulness was absolute for one inch and a half above the border of the ribs on the left side, and the upper border of the dull area as it crossed over to the right passed gently upwards and round to the nipple line in front. The uterus was anteverted, and there was some endometritis. I thought I could feel both ovaries, of about the usual size and in their proper positions, but somewhat tender to palpation. The patient said she seldom had any cough or expectoration. At the right apex there were some crepitations heard on auscultation, but otherwise the lungs were normal. The apex beat of the heart was displaced upwards and to the left, but the cardiac sounds were normal, and the pulse was fairly strong, beating 64 to the minute. The action of the bowels required to be assisted by medicine and the patient was thin and losing flesh, but except for the conditions related she seemed to be a healthy woman. The kidney action was good. There was nothing in the patient's history to show how she had become infected by hydatids; she had lived in Woolwich all her life, and said she had never had anything to do with dogs or animals of any kind. Her husband was a waterman.

I operated on Feb. 17th, 1891, making an incision in the middle line of the upper part of the abdomen. After exploring the parts I first removed the growth from the left loin. It lay in the connective tissue behind the peritoneum, its connexions being easily separated except posteriorly, where they were more dense and much more vascular, so that

numerous vessels required to be ligatured, although I did not tie them until the end of the operation in the hope that pressure by forceps might arrest the bleeding. I attempted to remove the cyst unopened, but I had to use a good deal of force, and it unfortunately burst. There was little of the contents spilled over the peritoneum, however, because the sac was ruptured by considerable pressure, and the fluid was in great measure, if not entirely, discharged outwards. The tumour consisted of a single sac, having the characteristic lining of membranous tissue formed by the parasite surrounded by the usual adventitious fibrous capsule developed by the host. It contained no daughter cysts. I next took out the smaller of the cysts below the liver. It seemed to be outside this organ, but connected with it by a kind of pedicle, which I tied as I would tie the attachment of an ovarian tumour. This hydatid contained daughter cysts. The largest of the tumours was in the liver substance. I cut into it and removed much fluid and numerous daughter cysts, taking great care to keep the peritoneum clean by means of sponges packed round the opening. When I had removed most of the contents of this cavity I again explored the abdomen and found that there was a chain of hydatids running backwards along the lower surface of the left lobe of the liver. Some of these I enucleated, but the manipulation became more difficult as I had to follow the cysts deeper, and when the patient had been about three hours on the table I felt compelled to desist from further attempts. It was obvious that there were more cysts in various parts of the peritoneum, and that there were other cysts in the liver substance. A very long time would have been necessary to deal with them all, and the patient's condition did not warrant a continuance of the operation. I was, however, able to separate two of the chain of hydatids at which I was working without opening either of them. I washed out the empty cyst cavity in the liver with iodine and water, sewed its opening to the opening in the abdominal wall so as to make a sinus, and closed the rest of the incision in the usual way. Two drainage-tubes were passed through the sinus into the cavity, and the wound was dressed with a large quantity of carbolic gauze. The patient was on the operating table nearly three hours and a quarter. She quickly recovered from the chloroform, and convalescence took place without causing any serious anxiety. The temperature rose to 103.6° F. in the vagina and the pulse to 120 twenty-four hours after the operation. The temperature then fell and fluctuated between 99.6° and 101° for three weeks, after which time it was below 100° and the pulse was below 90. There was some difficulty with the bowels during the first nine days; but afterwards they moved freely, and the patient then had only to contend with the weakness natural after such an operation and with some bronchitis. The discharge from the wound was never very copious, but the incision did not completely heal for nearly three months, although long before this the patient had gained strength and put on flesh, and was able to get about freely. She left the hospital in the eleventh week after the operation. She remained under my observation, and soon after she went home the upper part of the right side of the abdomen began to enlarge again, and there was much colicky pain in the abdomen, especially after food. The bowels still required to be assisted by laxatives, but they acted better than before the operation. Menstruation was regular.

The patient was readmitted to hospital on Nov. 20th, 1891, nine months after the first operation. The right costal margin was then much more prominent than the left, the greatest measurement from the spine to the middle line in front being seventeen and a half inches on the right side and sixteen inches at the same level on the left. The scar was very wide at the part where the tubes had been, and was dragged considerably to the right of the middle line. To the left of the scar, and close to the costal margin, there was a rounded swelling measuring about two and a half inches across and standing about an inch out from the surface of the abdomen. To the right there was a large, smooth, rounded swelling reaching well down towards the pelvis and filling the whole of the right side. These swellings exhibited the thrill on percussion that is characteristic of hydatids; they were evidently in, or closely connected to, the liver and they were dull on percussion except at their lower margins, which were rounded and partially overlapped by the intestines. Above the costal margin the percussion note was absolutely dull as high as the level of the nipple in front, and was impaired up to

the second intercostal space on the right side. The absolute dulness behind was bounded above by a line crossing the middle line at the level of the spine of the sixth dorsal vertebra, and gradually curving downwards on the left. The lungs were very greatly compressed, and there was considerable cyanosis, but I detected no signs of active lung disease, and although there was a slight cough there was no expectoration. The heart's action was fairly good, the pulse usually beating 72 times to the minute. The apex beat was felt six and a half inches from the middle line in the fifth interspace. The temperature was normal or sub-normal. In the right side of the pelvis a small tumour was felt by bimanual examination, exactly resembling an ovarian tumour and about the size of an orange. On Dec. 2nd I carefully opened the abdomen by removing the old scar. After freeing some omental adhesions I exposed the smaller and more prominent cyst. This I aspirated, laid open, and cleared out in the same way as I had treated the liver cyst at the first operation. It contained numerous daughter cysts. When all was clear I made a careful examination of the abdomen and found a number of small tumours low down in the pelvis. I counted five. Leaving them I returned to the liver and cut into the large cyst on its inner side, where it bulged into the one already opened. A very great quantity of fluid and daughter cysts was removed, but the bulk was not measured, as much of it was caught in towels and thrown aside. The size of this cavity may be estimated by the fact that after it was partially collapsed my sponge forceps, which measure eight and a half inches beyond the handles, did not reach a large part of the upper and posterior boundaries of the sac. It was with much difficulty that I got the parasitic sac of the main hydatid cyst away. This was very thick and firm, and would not fold up sufficiently to come through the opening until I had many times seized it and brought away small pieces. At last I succeeded in removing the bulk of it in one mass, but many small pieces were afterwards washed away with iodine and water. When the cyst was thus partially cleared the patient was so blue and collapsed that it was out of the question to attempt to remove the other tumours. I therefore sewed the opening in the liver to that in the abdominal wall, and closed the incision, draining the liver cavity and dressing the wound as at the first operation. This second operation lasted an hour and a half. The temperature rose to 102° on the day following the operation and again on the fifth day, the pulse on the first of these occasions being 120 and on the second 96. The respirations were not counted above 32 to the minute. There was an occasional cough and considerable dyspnoea, but very little expectoration, or other evidence of bronchitis. The lung resonance quickly increased, and there was marked tenderness on percussion over the upper surface of the liver for some days. The cyanosis and breathlessness disappeared very gradually, and the feebleness, which was extreme for more than a fortnight, was also slowly recovered from. The bowels again gave a good deal of trouble for a little more than a week, but when they acted freely the patient gained strength more quickly. The discharge from the liver was very profuse, and at times it contained a great deal of bile. Hydatid membranes escaped in considerable quantity at first, and later at intervals, the last observed coming away on Feb. 13th, 1892, two months and eleven days after the operation. On the twenty-fifth day the drainage-tubes, which had already been considerably shortened, were taken out and cleaned. The longest measured ten inches. They were gradually shortened, and on Jan. 20th one tube was removed. On March 18th there was only one small tube remaining, which measured two and a half inches in length. On March 3rd the patient was allowed to get up, but the wound was still discharging a large quantity of fluid, which was now of a thin, serous character. She went home on April 2nd, four and a half months after the operation. The wound continued to discharge very freely till about Christmas, 1892. About the beginning of December the quantity of discharge began to diminish and the wound healed very quickly and has given no trouble since; it had been open over thirteen months. When the wound healed the patient was about three months advanced in pregnancy, and I am inclined to think that the upward pressure caused by the enlarging uterus facilitated the healing of the wound. After the patient went home she had much colicky pain in the abdomen, but she said she felt better while carrying her last child than in either of her other pregnancies. After the child was born the patient

became weaker and thinner and had more pain, and on examination from time to time it was evident that the pelvic tumours were increasing in size.

The patient was readmitted on March 6th, 1894. At this time, except for the presence of the cicatrix, the abdomen was quite normal on inspection, but on palpation I mapped out three very tender rounded swellings in the right side, the lowest being close to the pelvis; the highest was the largest and was the size of a small orange. The whole abdomen was resonant on percussion and the liver dulness began at the level of the fifth rib and ceased a little above the costal margin below. By combined vaginal and abdominal examination I found that there were several cysts in the pelvis, but I was not able to say how many. The lungs were resonant everywhere, but the respiratory sounds were not nearly so free on the right side as on the left, and the patient now frequently suffered from bronchitis. On March 12th, two years and three months after the second operation, I again opened the abdomen, making the incision on this occasion below the umbilicus. The three tumours in the right loin and four in the pelvis were brought out and enucleated. Each consisted of a hydatid membrane, containing very little fluid, but full of collapsed daughter cysts and enveloped in an adventitious fibrous capsule. They were attached to subperitoneal connective tissue and to neighbouring structures. A fifth cyst in the pelvis was so closely connected with the back of the cervix uteri that I cleaned it out and drained it as I had treated the sacs in the liver. The cysts removed varied in size from that of a large orange to that of a duck's egg. Before closing the wound I examined the lower surface of the liver and found some more hydatids under the left lobe, evidently the remains of the chain I had felt at the first operation, but they had considerably enlarged. It was impossible to manipulate these through the incision already made, and I therefore cut directly down on them by a vertical incision a little to the left of the middle line and close to the ribs. Three hydatids were removed from close to the lower surface of the liver, two being about the size of duck's eggs and one the size of a sparrow's egg. The liver seemed to be of fairly normal shape and freely movable, having only loose adhesions to the scar, the upper end of which was considerably below the lower edge of the liver. Through these loose adhesions I felt a hard nodule which I thought was another small hydatid, but it was enveloped in adherent omentum, and as the operation was already a long one I thought it unwise to begin what might be a very troublesome and prolonged enucleation. This operation lasted over three hours, but it was not such a severe proceeding as either of the other two, and the patient was not so ill afterwards. During convalescence the highest temperature was 100·8° F. on the fourth day, and the highest pulse was 96 on the second day. The patient was almost free from fever and practically well after ten days, but there was a discharging sinus till June, when the wound finally healed. On leaving the hospital early in June the patient went to a convalescent home for a few weeks, and was very well while there; but after going to her own home she was for long troubled by a cough, sometimes accompanied by considerable expectoration. On Oct. 25th she came to see me on account of a small hernia at the lower end of the incision below the umbilicus. This had been noticed for five weeks, and was no doubt due to the persistent cough. The lungs were not dull on percussion anywhere, but the liver dulness was somewhat higher than it should have been on the right side posteriorly, and the respiratory murmur was everywhere very feeble. There were very few crepitations or râles, and at this time there was little expectoration.

I again saw the patient on Feb. 21st, 1895. She then complained of severe pains in the region of the liver, which had continued for about seven weeks and were very bad during the prolonged frost, but had been rather better since the weather became milder. On examination I found the abdomen quite flat; the incisions measured 3½ in., 3 in., and 2½ in. respectively, in the order in which they were made. The patient's cough had been much less frequent, and the hernia, which had been supported by a pad, was smaller and caused little trouble. The liver near the middle line was very tender to percussion and palpation. Through the scar of the second operation I could feel a hard nodule about the size of a bean, which seemed to be the chief seat of tenderness, and I have no doubt this was the hard substance I had felt at the end of the last operation. The liver seemed to be smaller than normal in front, but its dull area extended rather higher than usual behind. The lungs had

greatly improved, and, except at the right base behind, the air everywhere entered them freely. Since the severe pain in the liver region began some eight weeks previously the patient said she had lost flesh and she was very thin. It seemed as if some cyst were developing in or below the liver. I hope to keep the patient under observation, and if there is any further development I trust that I may be permitted to communicate the sequel.

(To be continued.)

THE PHYSICS OF CARDIAC SOUNDS AND MURMURS.

By JAMES T. R. DAVISON, M.D. EDIN.,

FORMERLY RESIDENT PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY.

MORE than twenty years ago Dr. Walshe wrote¹ that "the difficulty of unravelling the mechanism of the normal sounds of the heart is broadly and emphatically proved by the fact that from the time of Lennec to the present day some five-and-thirty theories, more or less completely differing from each other, have been proposed in its explanation." During these last twenty years the problem has still remained unsatisfactorily solved. I propose in the course of this paper to relate a few simple experiments which bear on the subject, and which appear to throw a great deal of light not only on the mechanism of cardiac sounds, but likewise on that of cardiac murmurs, and which, moreover, have the advantage from their great simplicity to be within everybody's reach. It will be advisable to study first the second sound. If after excision of the heart the aorta be firmly ligatured at a short distance from the semilunar valves, and the left ventricle having been opened, a stream of water be forcibly driven by means of an indiarubber syringe into the aorta from the ventricle, then the following takes place: the aorta becomes distended with liquid, and in the height of its distension the semilunar valves close in and shut the ventriculo-aortic orifice so that not a drop of water escapes back into the ventricle. From the ventricular side the valves are thus seen stretched by the fluid contained within the aorta. The semilunar valves have thus been shut by a forcible injection of liquid directed from the ventricle towards the aorta. In this experiment the ligature of the aorta is made to represent the resistance offered by the column of blood in the living subject; the stream of water injected forcibly into the aorta takes the place of the ventricular contents that normally pass into the vessel with each ventricular contraction; and, lastly, the indiarubber syringe is made to represent the ventricle. How is this closure of the semilunar valves brought about?

Physiologists hold that the semilunar valves are "probably closed almost immediately after the escape of the ventricular contents,"² and assign this closure to the refluxes produced by the negative pressure of the mere movement of the column of blood and by the elastic recoil of the arterial wall. Now, in the experiment just referred to the "negative pressure of the mere movement of the column of blood" cannot be a factor of the closure of the valves, for the simple reason that the ligature of the aorta prevents any such movement taking place. That the closure of the semilunar valve is likewise completely independent of the elastic recoil of the arterial wall the following modifications of the above experiment will plainly show. Let a part of the aorta together with the rim of the ventricle near the aortic orifice be dissected out; let a piece of linen be now sewn round the aorta from the level at which the extremities of the valves are attached to the wall of the vessel outwards, sufficiently close to prevent distension of the artery, but not too tight to occlude its lumen; if now, after ligaturing the vessel, water be forcibly driven into the aorta from the ventricular side the vessel fills with fluid and the semilunar valves close the orifice. Here no recoil of the arterial wall can come into play, inasmuch as its distension is prevented by the linen sewn round it, yet the valves close and shut the orifice. Again, if the aorta be ligatured as before, some distance beyond the orifice, and the ventricle having

been opened, a column of air is forcibly driven into the aorta from the ventricle by means of a gum elastic syringe, the following takes place: the vessel dilates somewhat, and the valves not only close in perfectly well, but even bulge prominently backwards towards the ventricle. Here, once more, no recoil of the arterial wall can explain the closure of the valves, as in order to produce this effect it is not necessary to drive the column of air too forcibly into the aorta so as to produce marked distension of the wall. The closure of the semilunar valves can thus be brought about irrespective of the refluxes produced either by the recoil of the arterial wall or by the negative pressure due to the mere movement of the column of blood. How, then, is this closure effected? The circumference of the aorta at the level of insertion of the extremities of the semilunar valves may be divided for purposes of description into three equal parts, the points of division corresponding to the points of insertion. If direct lines be drawn across these points of insertion an equilateral triangle will be described within the circumference of the aorta, the sides of the triangle corresponding to the loose edges of the semilunar valves. This is at once made apparent if, a part of the aorta having been dissected out together with the rim of the ventricle surrounding the orifice, dilatation of the vessel be effected by means of the fingers from both sides of the orifice at the same time. It is then seen that in the dilated state of the vessel a triangular lumen occupies the centre, and the space between the sides of the triangle and the circumference of the vessel is occupied by the somewhat lax semilunar valves. It is likewise to be observed that the edges of the valves in their lax condition dip downwards concavely between their extremities disclosing the aortic wall, which at this level is thinner and encloses a wider lumen than at the level of insertion of the extremities of the valves and upwards. When, therefore, water is forcibly injected into the ligatured aorta from the ventricle the wall of the vessel becomes distended; this distension, *per se*, by separating from each other the extremities of insertion of the valves, causes the edges of these to assume collectively the sides of an equilateral triangle, the interior of which forms the lumen of the vessel at its orifice, a space occupied by valvular surface being left between the sides of the triangle and the distended wall of the vessel. Now, according to Pascal's law, pressure exerted anywhere upon a mass of liquid is transmitted undiminished in all directions and acts with the same force on all equal surfaces and in a direction at right angles to their surfaces. Therefore, the same amount of liquid pressure that, acting at right angles to the wall of the aorta, produces its distension will also act at right angles to the exposed valvular surfaces which extend from the sides of the triangle to the circumference of the vessel, this exposure of valvular surfaces being due, as just stated, to the distension of the aorta. The liquid pressure on this exposed valvular surface will bring about the stretching of the valves; and this stretching of the valves in its turn forces them to adopt the pouch-like form which they owe to the concavity of their bases of attachment. The liquid pressure which is being transmitted equally in all directions tends to separate these pouches more and more from the sinuses of Valsalva, this separation from the sinuses causing the pouches to approximate each other, until at last they touch and close the orifice. But this approximation of the valves being due to their separation from the circumference of the vessel, and this separation being in its turn due to the fluid pressure which is being exercised in all directions by the water which is entering the aorta from the ventricle, it follows that the closure of the semilunar valves is effected solely by the injection of water into the aorta. During the height of the distension outwards of the aortic wall, does the distension inwards and backwards of the valves take place, both being effected by the same liquid pressure? The distension inwards and backwards of the valves being effected by the column of water entering the aorta, it is clear that this column (in its latter part) as it enters the aorta by this very act is closing the orifice against itself. When the last drop has passed the orifice the valves firmly close upon each other, this last drop being the end of that column of water which directly produces the closure of the valves. In that modification of the experiment, where the sewing of a piece of linen into and around the wall of the vessel from the level of insertion of the extremities of the valves upwards prevents the distension of the aorta from that level upwards,

¹ Dr. Walshe: Diseases of the Heart, p. 51.

² Text-book of Physiology (Foster), p. 246.

the injection of fluid, though unable to distend that part of the vessel, distends, nevertheless, the portion below it—that is, immediately behind the valves—and thus separates these from the sinuses of Valsalva, causing them to adopt the pouch-like form and eventually to close the orifice. But here also the closure is effected directly by the injected liquid.

The first experiment illustrates well what actually takes place in the living heart. The first effect of the ventricular contraction is to separate asunder the semilunar valves; the ventricular blood rushing into the aorta brings about the distension of this vessel. This distension, owing to the anatomical relations existing between the valves and the wall of the aorta, places the valvular pouches in conditions favourable to their being distended inwards and backwards by the same inrushing ventricular blood, this latter distension closing the orifice *pari passu* with the ingress of the last portion of the ventricular column, the ingress of the last drop being coincident with the firm closure of the valves. It is thus demonstrated that the semilunar valves are closed *directly* by the ventricular contraction before any negative pressure of the mere movement of the aortic column can come into play, and certainly before any recoil of the arterial wall is exercised. The contraction of the ventricle is then the direct cause of the closure of the semilunar valves. It has been alleged that during the contraction of the ventricle the semilunar valves are never kept perfectly separated from each other, but that their position is one of semiclosure during the act. Were this a fact then a murmur would always accompany the ventricular systole, for the alleged position of the valves would of necessity give rise to a murmur. In order that the semilunar valves may be even partially closed during the ventricular contraction it is necessary that the aortic wall be fully dilated first so as to afford a fixed support against which the fluid pressure can sustain itself while it reacts against all parts which are not fixed, and it is thus that it reacts against the semilunar valves until they attain a fixed posture in their closed state. But this full dilatation of the aortic wall cannot take place till the end of the ventricular contraction, for the first and greater portion of the ventricular column is expended partly in propelling the aortic column directly onwards, and partly in distending the aortic wall; it is only the latter and shorter portion of the ventricular column that brings about the full distension of the aorta, which extreme distension, as we have seen, must first take place before the fluid pressure brought about by the ventricular contraction can avail itself of the anatomical relations existing between the aortic wall and the semilunar valves, so as to commence and finish the closure of these valves. The semilunar valves are completely pushed asunder by the entrance of the ventricular column into the aorta, and it is only as the latter end of this column is leaving the ventricle that the valves rapidly close in and shut the aortic orifice. Such being the direct cause of the closure of the semilunar valves, it remains to ascertain what is the direct cause of the sonorous vibrations which, produced in these valves, give rise to the second sound.

It is generally held that the sonorous vibrations of the semilunar valves are effected by the recoil of the elastic aortic wall. It is easy to demonstrate that this view of the mode of production of the second sound involves a physical impossibility. If a small elastic balloon, such as children play with, be somewhat distended with water and then tied at its orifice, and if now the end piece of a binaural stethoscope be applied to any part of its surface, and pressure be suddenly made upon the balloon, the elastic membrane will bulge forcibly outwards at the point where the stethoscope is applied, but no sound will be produced. The same observation, with the same result, can be made with an ox's bladder; but in the case of the elastic balloon the thinness of the wall approximates itself more closely to the physical condition of the semilunar valves. The experiment can yet be more advantageously effected with a piece of the fresh small intestine of an ox. If a small piece of this intestine be somewhat distended with water, and after its two ends have been ligatured the end piece of a binaural stethoscope be applied to any part of its surface; if now, sudden and forcible pressure be made on any part of the intestine the other part will be rapidly and forcibly distended, but no sound will be emitted. It is thus demonstrated that a membrane possessing more or less the same physical characters as the semilunar valves does not emit a sound when it is forcibly distended by a mass of liquid which it encloses. The semilunar valves

being perfectly closed before the recoil of the aortic wall comes into play, and therefore, during that recoil, forming part of a membrane which encloses liquid, may receive a second distension owing to the mass of liquid which will be pushed against them by the recoil, but cannot through this distension be thrown into sonorous vibrations. The recoil of the aortic wall cannot, therefore, cause the semilunar valves to emit a sound. For the same reasons neither can the negative pressure of the moving aortic column be the direct cause of the second sound.

It might be supposed that the second sound could be produced by eddies created at the aortic orifice during the latter part of the passage of the ventricular column into the aorta; that these eddies would strike against the aortic surface of the valves, and thus give rise to the sound. That this is not so may be easily demonstrated. If a small piece of fresh intestine of an ox be filled with water and tied at both ends, and an indiarubber syringe be filled with a strong solution of permanganate of potash and in this state its nozzle be introduced into the intestine filled with water through one of its ends by loosening the ligature and then tying it tightly again over the nozzle; if now the intestine be held upwards against the light and the contents of the syringe be suddenly and rapidly injected into the intestine the wall of the intestine is seen to bulge outwards, the coloured solution is seen to go directly upwards and no eddies are seen to be produced immediately at the orifice of the nozzle. This observation can likewise be made with a transparent elastic balloon instead of a piece of intestine. It might once more be supposed that the second sound would be produced by molecular changes in the so-called fluid veins at the aortic orifice. Whatever be the character of the sonorous vibrations to which these fluid veins give rise, that they do not constitute the second sound may be demonstrated by filling a small piece of intestine with water, inserting into one of its ends the nozzle of an indiarubber syringe likewise filled with water, and firmly ligaturing both ends of the intestine; if now the end piece of a binaural stethoscope be applied to the intestine immediately behind the orifice of the nozzle and the syringe be rapidly compressed no sound whatever is heard at the indicated spot—in other words, the fluid veins have not given rise to a sound. Having thus shown how the second sound is not produced I will now endeavour to demonstrate what is its direct cause, and in doing so I will relate a very simple experiment which illustrates the mode of production of all cardiac sounds and murmurs.

Let a small piece of fresh intestine from an ox be filled with water, and through one of its ends let the nozzle of a good-sized indiarubber syringe, likewise filled with water, be introduced; let both ends of the intestine be firmly ligatured. If now the end of a binaural stethoscope (and this kind of stethoscope is recommended as it leaves the hands of the experimenter free) be applied to any part of the intestinal surface and the syringe be forcibly compressed no sound is heard, or at best only a very weak rumbling noise. If now the nozzle of the syringe, instead of lying in the axis of the intestine, be directed so that the column of water issuing from it strikes the intestinal surface at any angle whatever, the acoustic phenomena completely change. If the end piece of the stethoscope be now applied near the orifice of the nozzle, so that the column of liquid issuing from the nozzle will either strike it at any angle whatever, or will strike any portion of the intestinal surface between it and the orifice of the nozzle, the following acoustic phenomena are produced, according as the indiarubber syringe is compressed forcibly and rapidly or not. If the syringe is compressed rapidly and with some force a distinct highly pitched sound is produced; if the compression is effected with great force as well as rapidly, then a loud sound is produced, but of the same pitch as before. If the compression is effected slowly a soft blowing murmur is produced; if the compression be effected a little faster and with a little more strength, then a rough murmur is produced. The same observations can be made with an elastic balloon. If, instead of the thin-walled intestine, the experiment be performed with the thick-walled aorta of an ox, the same acoustic phenomena will be produced, with the exception that the sound emitted in this case is of a lower pitch than that produced in the case of the thin-walled intestine. It is therefore a physical law that when a membrane enclosing a liquid receives on its internal surface a stream which impinges against it, at any angle whatever, it will be thrown into sonorous vibrations, these vibrations giving rise to a sound when the stream

impinges with rapidity and force, the pitch of which sound will depend upon the relative thinness of the membrane (the thinner the membrane the higher the pitch), and the intensity of the sound will depend upon the force with which the stream is emitted; the vibrations giving rise to a soft blowing murmur when the stream impinges with little rapidity and force, and to a rough murmur when this rapidity and force are somewhat increased. These are principles the truth of which can be ascertained by everybody, as the elements with which the observations can be made are within everyone's reach. The question now arises whether the conditions which in the experiment give rise respectively to sounds of different pitch, as well as to murmurs of different character, are present in the normal and in the pathological heart. The answer will be seen to be in the affirmative.

It has been seen that during the first part of the ventricular systole the aortic orifice remains perfectly patent, and that it is only during the latter part of the contraction, after the aorta has been well distended, that the semilunar valves, owing to the anatomical relations already described, suddenly close in and shut the orifice. Now this sudden closure of the valves, taking place at the time when a stream of liquid is passing from the ventricle into the aorta, forces this stream to impinge against the ventricular surface of these valves; this stream being produced rapidly and suddenly by the rapid contraction of the ventricle, the semilunar valves being constituted by a thin membrane. Here are all the conditions present for the production of a high-pitched sound exactly similar to those which were present in the experiment with the indiarubber syringe and the intestine, and in point of fact both sounds resemble each other very much. There is, therefore, sufficient ground to conclude that the second cardiac sound is directly produced by the latter part of the ventricular contraction owing to the semilunar valves being thrown into sonorous vibrations by the latter part of the ventricular stream impinging against the ventricular surface of these valves in the act of their closing in. The degree of intensity of the second sound depends then solely upon the degree of hypertrophy of the respective ventricle; the pitch of this sound will depend upon the relative thinness of the semilunar valves. When these valves are normal the sound will be high-pitched, but when these valves become thickened through inflammation then the pitch will be lowered. The presence of an aneurysm *per se* cannot give rise to a real accentuation of the second sound; if the aneurysm protrudes forward then there will be an apparent accentuation of the second sound, simply because then the acoustic media of conduction are more favourable than normally for the propagation of the ordinary sound to the listening ear. Likewise high tension of either circulation *per se* cannot intensify the second sound. Under these conditions the second sound will be accentuated only when the high tension has caused the respective ventricle to hypertrophy. These are logical deductions from ascertained physical phenomena, which render more accurate the physical diagnosis of the conditions of the ventricular muscles and of the semilunar valves.

Now follows the examination of murmurs produced at the aortic orifice. Murmurs have been supposed to be produced by fluid veins created during the passage of a stream from a narrowed orifice into a wider channel. In the experiment described above, when an indiarubber syringe filled with water has its nozzle introduced into a piece of small intestine also filled with water and having both its ends ligatured, as long as the nozzle is held in the axis of the intestine the syringe may be compressed in any form and yet no distinct murmur will be imparted to the stethoscope placed over any part of the intestinal surface. Yet in this experiment having a stream issuing from the narrow nozzle into the wide intestine there are exactly the conditions which have been supposed to give rise to murmurs. The mode of production of a murmur is otherwise. As already described, if the nozzle of the syringe is directed so that the stream issuing from its orifice shall impinge against the intestinal surface, no matter at what angle, a high-pitched sound is heard when the syringe is rapidly and forcibly compressed, which changes into a murmur when the rapidity of the compression is diminished. It is demonstrated, therefore, as a physical fact, that a stream of liquid slowly impinging against a membrane will throw it into such sonorous vibrations that these will impart to the listening ear the sensation of a murmur. Stenosis of the aortic orifice is known to produce a murmur described as systolic murmur at the base. How is

this murmur brought about? The narrowing of the aortic orifice prevents the ventricle from contracting rapidly, because the ventricular column requires more time to pass through a narrowed than through a patent orifice. Again, in stenosis there is a surface of membrane which from the beginning of the ventricular contraction is so placed that it will receive against itself part of the ventricular stream as it passes through the narrowed orifice. There are here, then, the two necessary elements for the production of a murmur: a slow issuing—that is, a prolonged stream—and a membrane against which it impinges. If the prolonged stream issues forth with great force a rough murmur will result; if with less force a blowing murmur will take its place.

If an aneurysm with undistensible walls be situated just beyond the aortic orifice a murmur may occur during the contraction of the ventricle, not because a stream issues from a relatively narrow orifice into a wider channel, but because the want of distensibility of the aneurysmal wall is an actual obstruction to the rapid voiding of the ventricle, and it is an obstruction because, whereas normally a great part of the ventricular column goes to dilate the first part of the aorta, when this aorta, owing to an undistensible aneurysm, cannot distend, then the ventricular column must progress solely in an onward direction, which implies more time in the voiding of the ventricle. Again, owing to the undistensibility of the aortic aneurysmal wall, the fluid pressure caused by the entering ventricular column will from the very first have a fixed support against which it can sustain itself while it reacts on the unfixed semilunar valves, separating these from the aortic wall and tending to their closure. Under these conditions the semilunar valves will be partially closed during the greater part of the ventricular contraction. There are present, therefore, the two necessary elements for the production of a murmur—a prolonged ventricular stream and the semilunar membranous surface against which this stream will impinge during the prolonged ventricular contraction. It will be likewise seen that the same murmur must take place even in the absence of an undistensible aneurysm, provided that the aortic walls through disease are incapable of distension, and under this condition the murmur must take place although the semilunar valves be perfectly healthy. If the semilunar valves are completely destroyed and the aortic rim does not in any way protrude inwards so as to form a membrane, then the ventricular contraction cannot give rise either to a sound or to a murmur, for one of the necessary elements for the production of either a sound or a murmur is wanting here—viz., a membrane against which the stream can impinge.

(To be continued.)

DISTURBANCE OF THE CARDIAC RHYTHM AND PULSE

DUE TO IRRITATION OF THE ALIMENTARY TRACT, AND THE INFLUENCE OF OPIUM THEREON.

BY GORDON SHARP, M.B. EDIN.

IT is a well-known physiological fact that the vagus centre may be stimulated reflexly, producing slowing or stoppage of the heart, this stoppage being sometimes temporary, but at other times permanent. The nucleus of the fifth nerve and the nucleus of the vagus lie near each other, hence stimulation of the fifth nerve may stimulate reflexly the vagus and so affect the heart. But powerful stimulation of any sensory nerve may produce a similar result, as also stimulation of the sympathetic nervous system, especially the abdominal sympathetic nerves. Anyone who has performed physiological experiments knows that if a frog be pithed, the abdomen opened, and a coil of intestine sharply pinched the heart rhythm is often disturbed and there may be a momentary full stoppage of the organ, or, indeed, the stoppage may be permanent. During the past two or more years I have observed cases in which the regularity of the cardiac rhythm has been interfered with, due, I believe, to reflex stimulation of the vagus centre through the vagus nerve itself or through the abdominal sympathetic, most probably the latter. In all the cases the stimulating agent was in the shape of a catarrh of the stomach and bowels, or one of these, or the presence of some irritating body in the alimentary canal, or a constricting

body, or an inflammation of a part of the alimentary tract. In all, pain was a prominent symptom, and for the relief of this opium was employed, either in the shape of pill or tincture, and with beneficial effect as regards the pain and heart condition. This illustrates the value of pain as a symptom of disease, especially when the pain is severe. It calls for speedy relief, and the attainment of this places the patient on the high road towards recovery, and it gives the physician time and opportunity to investigate the true nature of the disease. Now abdominal pain is peculiarly amenable to treatment by opium, not the morphine salts or the expensive fanciful preparations bearing names borrowed from the ancient classics, but the old-fashioned drug. Morphine salts rapidly go the round of the circulation, and where one wants general analgesic effects they answer well, but where local effect is desired in the first instance the crude drug is the best agent to employ. The local action of opium in pain affecting the stomach and bowels is probably dependent on the fact that when it enters the stomach it forms (because of its astringency) a coagulum with the mucus, which is only again slowly broken up in its passage along the alimentary tract, but in the process of breaking up and setting free of the alkaloids an extensive local anæsthetic effect is produced. The result of this is the establishment of the fundamental physiological principle of repair of tissue—namely, rest. It must not be forgotten likewise that opium contains alkaloids other than morphine, and they, too, may play a part in this beneficial action. In addition, there is the astringency of the opium, which must check the secretion of mucus, and this of itself will stop peristalsis, and so another point is gained.

CASE 1.—A man aged sixty-six years was seized with vomiting and diarrhoea following an indiscretion in diet. Having known him for some considerable time I was aware that the heart and pulse presented nothing beyond what might be expected in a man of his time of life, but with the onset of the disturbance of the alimentary tract the heart showed signs of suffering and the pulse at the wrist was 120 and missed a beat in something like every thirteen. The diet was restricted to soda-water and milk, and ten minims of laudanum were prescribed every two hours till the condition improved. In twenty-four hours the heart and pulse had so much improved that only one beat was missed in every fifty or sixty, and with this the diarrhoea and vomiting had ceased. Further improvement followed, but I do not know that ever the pulse became quite regular again, for if the finger was kept on the pulse for a minute or two one beat was lost in every 150 or 200.

CASE 2.—I was called to see a man aged sixty years one afternoon about two o'clock. I had previously attended him and knew that four months before his heart was to all intents and purposes sound. He was the unlucky possessor of double hernia, which gave him no trouble. When I saw him he told me that he had severe pain at the lower part of the right lumbar region, and on examining him I found there was a tender spot of about the size of a penny. The bowels had been well moved some hours before my visit, and about an hour previously to my seeing him he had vomited green, bilious fluid. The pulse was most irregular and beat 86 in the minute. The intermission in the pulse was one in four, one in six, one in eight, one in ten or thereby, but never more than eleven beats followed one another without one being missed. The hernial sites were examined and the hernie found up. The diagnosis lay between a constriction within the abdomen or commencing inflammatory mischief of the bowel. To relieve the pain was the first consideration, and for this a one-grain opium pill was given at once, and five minims of laudanum were prescribed every hour till the pain abated. At the same time hot linseed-meal poultices placed between two layers of soft flannel were ordered, and were to be repeated every hour. I saw him six hours later and found that the pain had abated, and there was now only tenderness on touching the spot in the right lumbar region; but, what is more important as far as my present purpose is concerned, the pulse had undergone great improvement, and only one beat was missed in 40. In the next twelve hours one beat was missed in 60, and twenty-four hours later the rhythm was re-established.

CASE 3.—A man aged thirty-six years complained of pain in the right side of the abdomen in the line of the colon. The bowels were confined. Vomiting was present, but not severe. There was a certain amount of tenderness, although

this was not a prominent symptom. The pulse was only 48 in the minute at the wrist and was intermittent. The man expressed no desire to have the bowels moved, as is so often the case in peritonitis, and no purgative was given. A one-grain opium pill was given, followed in half an hour by five minims of laudanum, and the latter was to be repeated every two hours till the pain was removed or considerably relieved. At the same time poultices were repeatedly applied. Relief followed in a few hours, the pulse became regular, and the man recovered in some days.

CASE 4.—A man aged thirty-four years had severe recurrent colic, and on each occasion of the attacks the pulse was 50 to the minute, and every tenth beat was followed by intermission, which disappeared in every case after he had been placed under the influence of opium. After three relapses the condition was overcome and has not since returned. There was no reason to suspect lead poisoning.

In the first two cases the pulse was rather rapid; moreover, they were severe in type, and this may account for the comparative rapidity of the pulse. The two latter cases showed slow pulse and were not so acute, and would agree with what one would expect theoretically from a reflex stimulation of the vagus centre. In all, the interesting points are the intermission and the fact of it yielding so readily and effectually to opium. Details have only been mentioned in so far as they illustrate the points under discussion.

Grafton-street, Leeds.

MALTA FEVER IN RELATION TO LOCAL SANITARY CONDITIONS, AND THE HERMITE PROCESS.

By W. HILL CLIMO, M.D. Q.U.IRELL.,

BRIGADE-SURGEON-LIEUTENANT-COLONEL, ARMY MEDICAL SERVICE (RETIRED).

THE attention given at present to Malta fever both by the medical profession and by the general public is a sufficient indication of its importance and (paradoxical as it may appear) of the obscurity with which it has been surrounded. It is to the nebulous views which have prevailed as to its causation, and for which the medical profession is in a measure responsible, that is owing the want of sanitary effort to combat the disease. The history of Malta fever is strangely similar to what obtained a few years ago in reference to the increasing prevalence of, and mortality from, enteric fever in India. From time to time various explanations were hazarded to account for the phenomena connected with it; but they had to be discarded, and now the disease is admitted to be in every respect identical with the typhoid fever of European countries, being specific in origin, and traceable to a sewage-polluted soil affecting the water-supply. It is believed that in the near future a like view will be taken of Malta fever and its specific character recognised, the disease originating in local insanitary conditions, and the action of climate in its production being chiefly manifested by its influence on these conditions, and not directly on the constitutions of individuals in the first instance. In this view will be comprised all those diseases of the Mediterranean littoral which are of a febrile character, and which are associated with gastric or enteric symptoms. No observant traveller voyaging between England and Suez, taking Malta *en route*, can have failed to notice the grave sanitary defects of that island and its land-locked and tideless harbours. On all sides he sees conditions favourable to the spread and production of zymotic diseases. These are its geological formation, the nature of the soil, the density of the population, its imperfect scavenging, its water and food supplies exposed to the danger of sewage pollution, and its harbours made pestilential from floating excreta and organic debris of all kinds. The first two conditions may be taken together, for in this case the natural soil, where it exists, has been formed from the wearing away of the rock by climatic influences. About two-thirds of the island are cultivated, and the remaining third consists of barren rock. A shallow soil, imperfectly drained and largely saturated with organic refuse, presents every natural feature favourable to the production and development of the enteric germ. Added to this is the density of the population, which at present (exclusive

of the troops) is over 1330 to the square mile, and it is annually increasing. Much of the refuse is eaten by goats, which are kept in large numbers. It is a reproach to our modern methods of sanitation that nothing is done to arrest the increasing defilement. As long as the harbours of Malta are allowed to continue in their present state there must always be sanitary risk and danger to the public health. Moreover, as these conditions are mainly caused by our own navy and by our mercantile marine, while they are not remedied by what right can we impose sanitary obligations on the civil population? Certainly none. It is a case of putting our own house in order first. The proposal, then, is that the sewage &c. of our ships should be disinfected and rendered innocuous before being poured into the harbours of Malta by the electrolysis of sea water. No better locality could be selected for the trial of the Hermite process than in those harbours and in the Suez Canal. After much experience it is asserted that the health of passengers in troopships would be greatly improved if the ship's latrines, bilges, &c. were subjected to some such process as herein indicated; for, being fitted with steam engines, the cost of plant and of working would be trifling. Recent facts connected with the origin of typhoid fever from eating shell-fish poisoned by sewage in tidal waters give an emphasis to this question and accentuate its importance.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

AN ILLUSTRATION OF THE VALUE OF RECTAL FEEDING IN A CASE OF CARCINOMA OF THE STOMACH.

By HENRY WRIGHT, M.R.C.S. ENG., L.R.C.P. EDIN., I.M.,
MEDICAL OFFICER OF HEALTH, GAINSBOROUGH RURAL DISTRICT.

IN June, 1894, a man aged sixty-five years, who was accustomed to good living and led an active life, had an attack of influenza, followed by erysipelas of the scalp. These naturally enfeebled him very much, and as soon as he was able to get about again I sent him away for change of air. On his return I saw him, and he told me he had been suffering a great deal from dyspepsia, and it was plainly to be seen he was losing flesh very fast. I tried all I knew to relieve the trouble, but nothing did him any good, and, lastly, in November, I became convinced that he was suffering from carcinoma of the stomach, a diagnosis that was confirmed by Dr. F. J. Smith, who saw him in consultation with me on Nov. 15th, and who expressed the opinion that, judging from the severity of the symptoms and the extreme degree of emaciation, he would not probably live till Christmas. It soon became obvious that feeding by the mouth would be sufficient to maintain life but for a short time, since, beyond a little brandy, he only took one teaspoonful of peptonised milk every four hours, from Dec. 10th until his death, and very often could not even take that, or, if he did, could not retain it, on account of persistent vomiting. I then had to resort to rectal feeding, and used at first some of the ordinary nutrient suppositories, but they caused irritation of the rectum and the fæces were very foul-smelling. I then obtained some suppositories of "Mosqueras" peptonised beef-meat. One of these suppositories, containing sixty grains of peptonised beef meal, was administered three times a day from Nov. 27th, 1894, until the patient's death on April 30th, 1895, a period of over five months. The irritation of the rectum subsided and the fæces did not smell nearly so badly. Dr. Smith saw him again on Jan. 17th, 1895, and expressed his surprise at what the feeding had done for him, and said he thought they would keep him alive for some time longer. There can be no doubt whatever that they afforded an "immediate available supply of nourishment," for his pulse, which ranged from 90 to 105, was considerably improved in less than half an hour after the administration of a suppository. Unlike artificial fluid peptones, nutrient enemata, and other forms of suppositories, they did not cause any local or reflex irritation—in fact, they were not only tolerated, but the patient frequently expressed his

appreciation of their support, or, to use his own words, said, "I can feel those things feed me." His motions were regular and natural, and he was never troubled with diarrhoea. That his life was prolonged for at least three months, with practically no inconvenience to himself or others, there can be but little doubt, and further experience in other cases has confirmed my opinion that in them we have a very valuable and reliable adjunct to rectal alimentation.

Gainsborough.

NOTE ON "HEAVY BRAINS."

By J. A. CAMPBELL, M.D. GLASG., F.R.S. EDIN.,
MEDICAL SUPERINTENDENT OF THE CUMBERLAND AND WESTMORLAND
COUNTIES ASYLUM, CARLISLE.

I READ Dr. Middlemass's paper on a case of unusual weight of brain in THE LANCET of June 8th and particularly noted the quotations of recorded heavy brains. It may be of interest to put on record the experience of Garland's Asylum. A post-mortem examination has been made in the case of each death (except two) which occurred here since Jan. 1st, 1867. The total deaths during that time have been 1148 and the necropsies 1146. A record of each examination has of course been kept, and the weights of the viscera recorded in a uniform and systematic manner. I have looked over the brain weights and in the following table show certain facts concerning the instances in which the brain weighed sixty ounces or above that weight.

No.	Date of necropsy.	Sex.	Age.	Mental condition.	Weight of brain in ounces.
1	Jan. 8th, 1857	M.	33	Epileptic mania	62½
2	Dec. 26th, 1867	M.	28	Epileptic mania	62½
3	Nov. 4th, 1869	M.	44	Mania	60
4	May 22nd, 1871	M.	24	Epileptic dementia	71½
5	Nov. 3rd, 1873	M.	38	General paralysis	60½
6	April 17th, 1876	M.	61	Mania	60½
7	Sept. 23rd, 1876	M.	39	Mania	62
8	Dec. 16th, 1881	M.	38	Epileptic dementia	60½
9	Feb. 20th, 1883	M.	20	Dementia	60
10	March 18th, 1883	M.	71	Mania	65
11	Oct. 5th, 1883	M.	41	Dementia	62
12	April 9th, 1885	F.	65	Melancholia	62½
13	Jan. 23th, 1887	M.	55	Mania	63½
14	Dec. 18th, 1891	M.	37	Epileptic dementia	62½
15	July 15th, 1893	M.	36	Mania	61

I think that in the case of No. 4 the weight of the brain is so great that I give the measurements of the skull which were noted. The skull without the scalp measured 8½ in. antero-posteriorly, 8 in. diagonally, and 6 in. in width, and across the frontal bone at the junction with the parietal 4½ in. The following are points of interest: a third of the whole brains above sixty ounces were those of patients who had suffered from epilepsy, and though one at present hears so much of the increase of stature and general development of the female, yet only one female brain figures in the heavy list, though I have, and have had, females of gigantic proportions both as to length and breadth and of truly appalling weights. I may say that the population of Cumberland and Westmorland is recognised as one of big stature, and the brains should be proportionately large. I should, however, like to see some statement as to the Aberdeen size and weight of brain. It is said that Aberdonians take an exceptionally large size of hat. I merely give my experience of weight; I do not touch on the other topics, such as mental power and its relation to the size of the brain.

Garland's Asylum, Carlisle.

WESTERMARK'S OPERATION FOR UTERINE PROLAPSE.

By OTTO HOLST, L.R.C.P. LOND., M.R.C.S. ENG.

I VENTURE to call the attention of the British medical profession to a new operative treatment of this affection devised by a Swedish surgeon, Dr. F. Westermarck. In order to show the efficacy of his operation he takes the very worst

cases—cases which have resisted other treatment, even the operative treatment now in common use—i.e., anterior or posterior colporrhaphy, or excision of the cervix. Of such cases he has treated twenty-two with good and permanent results, requiring no subsequent employment of any pessary whatsoever. His method of operation is as follows: The patient being under the influence of an anæsthetic and in the lithotomy position, any hypertrophy or ulceration of the cervical lips is cut away, first the anterior and then the posterior. The bleeding is stopped with deep sutures, which are left long for subsequent use. The wounds in the lateral fornices, caused by the excision, remain open for the time being. Should a cystocele be present an elliptical piece of the vaginal wall (not only the mucous membrane), extending from the anterior lip of the portio vaginalis to within one centimetre from the urethral opening, is dissected up, and the wound closed by deep and superficial sutures. If now, by means of the long sutures left in the cervix, the prolapsed uterus be drawn to the right side, the left lateral attachment of the vagina to the paracervical and paravaginal connective tissue becomes well marked. An incision is then made along the anterior fold thus made apparent, beginning from the anterior end of the wound left open in the cervix, and extending straight down the side of the vagina to within about three centimetres of the vaginal opening; parallel with this, and from one to one and a half centimetres behind, another incision is made from the posterior end of the cervical wound. These incisions meet below at an acute angle. The intervening piece of the vaginal wall is dissected up, so that the subjacent connective tissue lies exposed. The bleeding is stopped and deep sutures are inserted, but not tied. The uterus is now drawn over to the left side and the same performance repeated; the womb is then pushed up and the sutures on either side are tied. If the perineum be imperfect, a perineorrhaphy, according to the principles laid down by Tait, is performed. The novelty in this method of treatment lies in the operation of colporrhaphy being lateral. Dr. Westermarck's reason for this modification of operating is that it is the strong connective tissue in the broad ligaments which keeps the vagina *in situ* even when the perineum is imperfect, and not the connective tissue found between it and the bladder anteriorly, and the rectum posteriorly. That this view is correct is shown by the fact that prolapse of the anterior and posterior vaginal walls occurs without corresponding prolapse of the bladder or rectum, as the case may be. This is no doubt due to the loose and lax condition of the connective tissue found in these situations. He compares the relation between the uterus and the vagina to a funnel hanging down the neck of a bottle, and contends that, the uterine ligaments—i.e., the upper part of the broad ligaments, the round ligaments, and the sacro-uterine ligaments—being too feeble to keep the uterus in position, it is the lower part of the broad ligaments and their strong connective tissue which keep it *in situ*.

Eastbourne.

AN UNUSUAL FORM OF STRANGULATED HERNIA.

By DONALD F. SHEARER, M.B. OXON., F.R.C.S. ENG.

THE patient who forms the subject of this communication was a weakly woman sixty-two years of age, who had worn a truss for a right inguinal hernia for several years. On two previous occasions she had been under my care for apparent strangulation, which I was able to reduce after the application of an ice-bag. On this third occasion, when I saw her at 11 A.M., the hernia was as large as a goose's egg, quite dull, and very tender. She stated that it came down about 2 A.M., and that she had been unable to get it back, although she had kept ice on it since 6 A.M. I found it was not possible to reduce it, and left it under an ice bag till 6 P.M., when, with the assistance of Mr. Sidney Turner, she was put under chloroform, and a further unsuccessful attempt made to reduce the rupture. I then cut down on the sac, and found that it was full of clear fluid, with a knuckle or two of gut protruding through the internal ring into a dilated canal of Nuck. The gut, which was dark red and congested, was easily returned when the pressure of the fluid was removed without incising the neck of the sac. The cause of the strangulation was then obvious. The internal ring had, by repeated descent of the hernia, been invaginated into a distended sac to the extent of nearly an inch, causing a

circular depression around and above it, into which the prolapsed intestine had been forced, and subsequently compressed and strangulated by the increasing fluid. The sac was removed, and the neck ligatured as high as possible. The patient recovered satisfactorily.

ST. THOMAS'S HOSPITAL.

CARCINOMA OF THE URETHRA AND BLADDER; REMOVAL OF THE GROWTH, WITH CLOSURE OF THE RESULTING SUPPUBIC WOUND, AND ESTABLISHMENT OF PERMANENT SUPRA-PUBIC DRAINAGE.

(Under the care of Mr. W. H. BATTLE.)

PRIMARY carcinoma of the peri-urethral tissues in the female is a rare disease, and little has been written about it. There are many monographs on urethral caruncle, but few on other new growths of this part. The contrast between the symptoms produced by the growth in this case and the distress caused by the much less dangerous urethral caruncle is very marked. In the former there was merely pain when the bladder became over-distended in consequence of the mechanical obstruction caused by the growth; in the latter the symptoms are very severe and occasion great distress, resembling very often those produced by stone, and are not infrequently increased by a cystitis. We have only found one case recorded of similar disease in which the same method of operation was carried out. Dr. J. H. Dunn¹ had a patient under his care for recurring malignant disease which involved the bladder, vagina, external genitalia, and inguinal glands. He operated in two stages: firstly, he removed the inguinal glands and performed the first stage of a cystotomy, the bladder being opened on the fifth day; he then removed the growth and sutured the bladder wall in front to that behind. The treatment of the resulting wound in the bladder differed from that adopted in the following case. The condition of the patient was satisfactory five months after the operation. "By using a catheter four to five times in twenty-four hours she was comfortable and in perfect control of the urine, and never soiled by overflow day or night." The account of this case is from the notes of Mr. Wheeler, dresser.

The patient, a widow aged sixty years, who had had children, was sent to Mr. Battle in the out-patient department by Mr. Sydney Fairland on March 20th, 1894. She was a stout, red-faced, emotional woman, who complained of pain, the result of being unable to pass urine. She had had attacks of retention of urine on and off for from three to four months for which she had to seek medical advice. There had not been much pain, excepting when the bladder became distended, then the pain was very severe. A catheter had frequently been required to give relief. She had not noticed any vaginal discharge or unusual swelling, had not lost flesh, and her general health was good. The family history was indefinite. She had not suffered from any serious illness. As the woman was suffering from retention of urine and was in considerable pain she was sent up to the ward at once and relief was afforded by catheterism. The urethra was the site of a new growth, which was evidently the cause of the obstruction. Further examination next day showed this growth to be very hard, rounded, and nodular, completely surrounding the urethra along its whole length and reaching up to the bladder. The finger could be just passed beyond the limits of the growth, which was movable over, but in close relation with, the ramus of the pubes on each side. No ulceration could be detected, and there was no area of softening, the mass being of uniform firm consistence. There was no bleeding when the catheter was passed. There was no abnormal enlargement of

¹ Annals of Surgery, 1894, vol. i., p. 961.

lymphatic glands to be detected. The urine, withdrawn with a catheter, was thick, with a deposit of muco-pus, and showed about a third albumen; there was no blood. The abdomen was well covered with fat and had thick walls. The patient appeared to be quite healthy, excepting for the growth and its effects. Until the operation it was always necessary to draw off the urine with a catheter, the patient becoming much distressed at times from the retention, and quite unable to pass urine without assistance. On March 22nd she was placed under the influence of ether and a supra-pubic cystotomy was performed. The bladder was washed out and then injected with a small quantity of boracic acid solution. No rectal bag was used. After incision of the bladder wall the sides of the incision were sutured to the edges of the skin wound on each side. A large drainage-tube was placed in the bladder, and the upper part of the wound was brought together with silk sutures. The patient was then placed in the lithotomy position and the growth fully exposed by the use of Sims's speculum and retractors. An incision was made on each side from before backwards; the one on the right side extended to the bone; these were joined in front by a curved incision following the arch of the pubes in front of the clitoris; the whole of the mass beneath the pubic arch, including the attachments of the clitoris, was now rapidly dissected back, the bone being bared. The upper limits of the growth were more accurately defined, and it was removed with the scissors by cutting through the bladder beyond it. The invasion of the bladder by the growth had extended further along the anterior than along the posterior wall, and as the section had gone through the edge of the growth in front, an additional inch or more of the anterior wall required removal, leaving an opening through which three fingers could be passed. The bladder was in a condition of subacute catarrh. After the arrest of hæmorrhage, which was comparatively slight in amount, the posterior wall of the bladder was drawn forward and attached to the anterior edge of the wound by means of wire sutures. There was some tension on the stitches towards the right side of the wound, but the bladder was completely closed by the sutures, which brought the edges well together. Iodoform was used to the wounds, iodoform gauze was applied to the supra-pubic wound around the drainage-tube, and plugs of the same gauze were placed in the vagina. Two days after the operation she developed bronchitis, and the temperature rose to 103° F. at night. She was delirious, abusive, excited, and tried to get out of bed at night. It was difficult to manage the supra-pubic tube, as she tried to pull it out and interfered with the flow of urine through it. Possibly in consequence of obstruction to the flow thus caused some leakage took place from the subpubic wound. There was no sloughing. On the 30th the wire stitches were removed. The wound had closed very well, excepting to the right of the middle line close to the pubic ramus, where there was a small sinus surrounded by indurated tissue. Syringing with boracic acid lotion was carried out daily. She was still very noisy at night, but quieter during the day; the temperature had been generally above 103° in the evenings of the days which had intervened since the 24th, but the condition of the chest was improving. By April 3rd the temperature had become normal and the previous condition of excitement was followed by a period of depression, with low temperatures. The bronchitis cleared up, and the subpubic sinus diminished in size after the application of solid nitrate of silver. It had not closed entirely when she left hospital on May 23rd, but was not larger than a crow's quill at the surface, and the leakage was very slight when she walked about, but she refused to have anything done to close it. There was no evidence of glandular infection. She was in good health bodily and mentally, and apparently quite able to manage the apparatus (Buckston Browne's), which answered its purpose admirably. Microscopical examination of the growth showed it to be a carcinoma without cell nests.

Remarks by Mr. BATTLE.—I have been called upon to treat several cases of malignant disease (chiefly epithelioma) of this region during the past few years, in some of which the urethra had become involved in extension of the growth. In the removal of these growths it proved possible to do the operation without impairing the action of the sphincter. The question as to what would be the best course to pursue should it be necessary to remove the whole of the urethra had necessarily presented itself. In the excision of growths of malignant character from this part of the body it is

advisable to make a free removal, otherwise the disease will speedily recur. It was probable, therefore, that a case might apply for relief in which removal of the growth would result in a condition of permanent incontinence of urine. Some months before this case came under care I had considered the question of the treatment which it would be advisable to follow, and had decided to act in the way described. Had the bladder been much inflamed I should have done the supra-pubic operation some days before proceeding to excise the growth, for I had some fear lest an unhealthy mucous membrane with decomposing urine should interfere seriously with the healing of the subpubic wound, and possibly cause a spreading inflammation in the cellular tissue about the bladder. As the cystitis was but slight, I completed the operation at one sitting. Since the patient went out of the hospital I have heard nothing from her; before she left she was far happier than when admitted, and appeared able to manage the apparatus quite satisfactorily. It might, however, be possible to arrange so that the bladder should be emptied at intervals and the necessity for wearing constantly an apparatus, such as that supplied, done away with. The mental condition after the operation was that of an insane person, and it is interesting to note that such a state of mind has most frequently followed operations on the genito-urinary organs. The character of the delirium was not accounted for by the severity of the bronchitis or by any apparent septic condition of or about the wounds. My best thanks are due to Mr. A. R. O. Milton, the house surgeon, for his great care of the patient.

LEEDS GENERAL INFIRMARY.

INTESTINAL ANASTOMOSIS BY THE MURPHY BUTTON FOR RELIEF IN AN ADVANCED CASE OF CANCER OF THE COLON AND STOMACH; NECROPSY; REMARKS.

(Under the care of Dr. A. G. BARRS and Mr. MAYO ROBSON.)

ALTHOUGH in the following case life was probably neither materially lengthened nor shortened by the operation performed, it seems to be desirable to report it as an example of a comparatively new method of treatment in a patient extremely ill and unable to bear a prolonged operation.

A man aged sixty-five years was admitted under the care of Dr. Barrs on March 25th complaining of abdominal pain, vomiting, and constipation, the pain having been present for nine months and the vomiting for a fortnight. During the latter part of his illness he had rapidly lost weight, decreasing from 14 st. to 10 st. 12 lb. On admission the patient looked ill and emaciated and the abdomen was generally distended. He complained of pain in the region of the umbilicus, the pain being increased by food and relieved by the vomiting which shortly followed the taking of anything solid. An ill-defined hardness was felt under the left ribs, though there was no tenderness here or elsewhere in the abdomen. No peristalsis was visible. Though a little flatus was passed, after the rectum had been cleared by enemata no proper action of the bowels occurred. The tongue was coated. Mucous râles and emphysema of the lungs were noted. The urine was normal. Dr. Barrs diagnosed the case as one of intestinal obstruction, probably dependent on growth, and advised operation, the patient being transferred to the surgical wards on March 29th, under the care of Mr. Mayo Robson, who opened the abdomen the same day by a three-inch incision in the middle line below the umbilicus. Exploration showed a large tumour on the left of the spine involving the splenic flexure of the colon and the stomach, and being too extensive for removal even if the patient had been in a condition to bear a prolonged operation, which he was not. The ileum and sigmoid flexure of the colon were therefore brought into the wound, surrounded by an elastic tourniquet, and made to communicate by means of a medium-sized Murphy's button, after which the abdomen was closed. The anastomosis occupied a little under five minutes, the time being noted without the operator knowing this was being done. The parietal wound was united by silkworm gut sutures. No shock followed, and after the ether sickness had passed off there was no further vomiting. The wound pursued an ordinary course and the sutures were removed on the seventh day. Flatus was passed on the second day and the bowels were moved by an enema on the third day. Prepared food, milk, and other light diet were given from the second day onward. There

had been a little cough and expectoration throughout, and on April 2nd the patient complained of his chest. The temperature remained normal and there were no abdominal symptoms, but the hypostatic congestion of the bases of the lungs and purulent expectoration increased in spite of stimulants and propping up in bed, and he quietly succumbed on April 9th, eleven days after the operation. Post-mortem examination showed hypostatic congestion of the lungs and entire absence of peritonitis. A free opening was found between the ileum and sigmoid flexure of the colon. The detached button was found in the cæcum. The connexion between the ileum and colon was quite secure, but easily detachable, as there had been very little inflammatory reaction, and the margins only of the two apertures in the gut were united. The cancerous mass had completely blocked the splenic flexure of the colon and was adherent to the stomach and omentum.

Remarks by Mr. MAYO ROBSON.—The case illustrates, first, the ease and rapidity with which anastomosis by means of Murphy's button can be effected even in the presence of general distension of the intestines; secondly, the slight amount of shock following a short operation on the intestines even in a patient extremely debilitated by disease; and, thirdly, the very slight amount of inflammatory reaction caused by the sloughing out of the button and, therefore, the slender bond of union between the connected loops. In this case the button fell into the bowel on the proximal side of the stricture, and, therefore, the stricture being impassable, it could not have been parted with. Although in an incurable case this was a matter of no importance, in other cases the imprisonment of the button might make a great difference to the patient. I should think that the difficulty might be overcome by making the distal flange of the button slightly larger than the proximal. The button has been so successfully employed by the inventor and by others that it now must form a necessary part of the armamentarium of all surgeons who perform abdominal work; though, like others who have written on the subject, one cannot help feeling the undesirability of leaving large foreign bodies inside the alimentary canal. The great advantage possessed by the button is the rapidity with which it can be employed. Where, however, such haste is not necessary, as in many cases of enterectomy for new growths and other similar procedures, I still prefer the use of the decalcified bone bobbin, which I have hitherto found of so great service.

LOUGHBOROUGH AND DISTRICT GENERAL HOSPITAL AND DISPENSARY.

OVARIOTOMY FOR MULTICULAR CYST; RECOVERY, COMPLICATED BY FEMORAL HERNIA; REMARKS.

(Under the care of Mr. J. B. PIKE.)

THE following case is an example of the rare complication of strangulated femoral hernia after the removal of a large ovarian tumour. For the notes we are indebted to Mr. A. Palmer, house surgeon.

The patient, a feeble edentulous female stating her age to be sixty years, but looking more like seventy, was admitted to the Loughborough and District General Hospital early in June, 1894, for the treatment of a tumour which nearly filled the abdominal cavity. The growth had been very rapid, and it had not attracted her attention until about six months before her admission. Percussion gave dulness anteriorly, extending more to the right side, and resonance in both flanks. The uterus was movable, and fluctuation could be felt in Douglas's pouch. An ovarian cyst with several compartments was diagnosed, and ovariectomy was performed by Mr. Pike on June 10th, with the assistance of Messrs. Eddowes, Corcoran, and Phelps. The tumour having been exposed by an incision extending from near the umbilicus to within about two inches of the pubes, a large anterior cyst was tapped with Wells's trocar, and seven or eight pints of fluid were evacuated. With slight traction a second cyst came through whole, and this was incised and carefully emptied. No adhesions could be felt, but the tumour still did not present itself. Mr. Pike therefore enlarged the opening in the second cyst by tearing with the fingers, and passed his hand into it. He was thus able to break down the remainder, and by squeezing it in the hand to draw it through the opening. This portion was multilocular, containing thick gelatinous matter. No fluid

escaped into the abdomen. The pedicle was thin and was ligatured by transfixion with a blunt needle. The cavity having been sponged out, a Keith's tube was inserted and the wound closed with silk sutures. The tube was removed on the third day with some difficulty, a band of lymph having insinuated itself through one of the perforations and requiring to be snipped through with scissors. The patient suffered from severe shock, but rallied quickly, the wound healing by first intention and the temperature scarcely rising above 100° F. On the 27th the patient was attacked by bilious vomiting, with severe symptoms of shock, almost amounting to collapse, which caused considerable anxiety as to the lymph bands which might possibly exist in the pelvis. This was found to be due, however, to a small femoral hernia, which had not descended as long as the tumour was *in situ*. The hernia was reduced by taxis, and since then the progress of the case has been satisfactory.

Remarks by Mr. PIKE.—This case appears to be of interest on account of the feeble condition of the patient and the very misleading complication during convalescence. I attribute the success of the operation to strict asepticism; to only one person's hand entering the abdomen, that one hand having been frequently cleansed with perchloride of mercury solution during the operation; and to the care bestowed upon the case by our house surgeon and nurses.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Special General Meeting.—Further Observations on the Development of Mammary Functions by the Skin of Lying-in Women—Intra-peritoneal Rupture of Bladder successfully treated by Suture.

A SPECIAL general meeting of this society was held on June 11th, Mr. HUTCHINSON, President, being in the chair, for the purpose of electing a treasurer in the room of the late Surgeon-General J. A. Bostock, C.B. The Council nominated Mr. J. Warrington Haward for the office, and he was duly elected.

The last ordinary meeting of the society for the present session was then held.

Dr. CHAMPNEYS and Mr. BOWLBY contributed a paper on Further Observations on the Development of Mammary Functions by the Skin of Lying-in Women. Reference was made to the previous paper¹ containing a record of thirty cases, and the description of the lumps there given was quoted. The opinion there expressed was that the lumps were developed from the sebaceous follicles of the skin. Three sets of specimens had since been obtained and subjected to microscopical examination. They were seen to consist of (a) a covering of normal skin; (b) loose subcutaneous tissue and fat; and (c) aggregation of glands. The glands were situated deeply, in the situation of sweat glands, and much more deeply than the sebaceous glands, which were seen unaltered. The glands were of the tubular type, the deeper parts much convoluted, the terminal ducts nearly straight and opening through interpapillary processes. The cells of the deeper parts appeared to be columnar; those of the duct were polyhedral, in two or three layers. The glands, in short, were like sweat glands, but extended more deeply, were more irregular both in structure and extent than those in normal skin, and were interpenetrated by plentiful unstriated muscular fibres; they formed the lumps in question. There was no appearance of mammary tissue or any other tissue except that described. They agreed in microscopical appearance with the description of skin glands in the human axilla by Dr. Creighton.² The conclusions drawn were (1) that the lumps consisted of modified sweat glands; and (2) the fact that various mammary secretions were produced by modified sweat glands seemed to show either that mammary tissue was not necessarily a direct modification of sebaceous gland tissue or that similar secretions could be produced by more than one variety of skin

¹ Transactions of the Royal Medical and Chirurgical Society, vol. lxxv. p. 419.

² *Ibid.*, vol. lxx.

gland. In this connexion it might be remembered that the ceruminous glands of the ear which secreted "wax" were coiled-tubular and not acinous in structure.—The PRESIDENT remarked that the axilla was the common seat of a peculiar disease affecting the female—namely, the succession of a series of abscesses. It was probable that these arose in the glandular structures described.—Mr. GODLEE remarked that he had once been surprised at finding this glandular tissue in an axilla which he was examining in connexion with scirrhus.—Dr. MITCHELL BRUCE called attention to the fact that atropine powerfully affected both the mammary and the sudoriferous glands by arresting their secretion, while pilocarpine powerfully stimulated both sets of glands, and also the ceruminous glands of the ear.—The PRESIDENT inquired if Dr. Champneys and Mr. Bowlby had examined the glands of the ornithorhynchus, which animal had no proper mammary glands.—Mr. BOWLBY, in reply, said that they had not examined the glands of the ornithorhynchus, though Dr. Creighton in his paper had pointed out their analogy to those of the dog and of the human axilla. The difference between the glands described and those of normal skin was one of size and not of structure. The gland elements became hypertrophied together with the adjacent fat, and these formed the lumps found in pregnant women.—Dr. CHAMPNEYS, in reply, said that he had seen these lumps acquire the size of a hen's egg in the axilla.

Mr. WALSHAM related a case of Intra-peritoneal Rupture of the Bladder in which Suture was followed by Recovery. He also made remarks on the inflation test. He said that in 1888 he read before the society a case of intra-peritoneal rupture of the bladder successfully treated by suture, supplementing the paper with a table of 11 cases, all he could find published, of that injury treated in like manner. He now related a second successful case, and Mr. Miles, late house surgeon to the Metropolitan Hospital, had collected 17 additional cases in which suture was employed, making altogether 28 published cases of intra-peritoneal rupture of the bladder treated by suture. The patient, aged forty-two, was admitted into the Metropolitan Hospital on March 8th, 1895, with an intra peritoneal rupture of the bladder. The diagnosis was established by inflating the bladder with a few cubic inches of air forced in by two or three compressions of the rubber ball of an ether-freezing microtome. The abdomen at once became tympanitic and the liver dulness effaced. The rent was closed by fourteen silk Lembert sutures, the pelvic cavity irrigated with perchloride of mercury and boracic lotion, and the abdominal wound sewn up after the bladder had been proved competent by injection with milk. An uninterrupted recovery took place. The value of the inflation and injection tests for ruptured bladder was discussed. The present appeared to be the first case in which the inflation test had been actually put into practice. The conclusions drawn from a single experience were: (1) that the amount of air to be introduced need only be very small, not more than three or four cubic inches; (2) that only very moderate pressure was required for the inflation; (3) that the presence of quite a small amount of free gas in the abdominal cavity was sufficient to establish the diagnosis beyond a doubt; and (4) that the introduction of gas into the abdominal cavity, even in small quantity, was attended by a profound disturbance in the patient's general condition. The disturbance which followed in this case at once passed off on opening the abdomen and allowing the free air to escape. It was suggested, therefore, that the test in future should not be applied till the patient was on the operating table, so that should the collapse threaten life the abdomen could be opened at once. In the after-treatment of the case it was contended that a catheter should not be left in the bladder: firstly, because it was not necessary; and secondly, because of the risk of cystitis and septic infection. Of the 28 cases included in the two tables 11 recovered and 17 died. In the 11 that recovered, in only 1 was peritonitis present at the time of operation; whilst conversely in the 17 that died in 8, and probably in 9, peritonitis had already set in. The cause of death in the 8 cases in which there was no peritonitis at the time of operation was in 5 shock or hæmorrhage, or the two combined, and in 3 peritonitis, the peritonitis in 2 out of the 3 being due to leakage of the rent or giving way of a suture. In no less than 4 out of the 28 cases was the bladder found at the post-mortem examination to leak. The importance of testing the competency of the bladder by injecting milk or other bland and easily detectable fluid could not therefore be too strongly urged.—

The PRESIDENT congratulated Mr. Walsham on the ingenious expedients he had resorted to in order to make the diagnosis certain. The success of these operations evidently depended upon attention to small details, and one of these details was the use of a proper needle. He himself had closely watched many interesting cases of rupture of the bladder which illustrated the tolerance of the peritoneum in some cases to considerable urinary extravasation. He had never sutured a ruptured bladder, as his experience of them lay in the days before this was a recognised procedure.—Mr. BAKER asked why it was that the injection of three or four cubic inches of air into the abdominal cavity produced these very serious symptoms. He thought that other factors were probably at work to account for the symptoms of collapse. The structures within the abdomen were constantly subjected to varying degrees of pressure without producing constitutional reaction, and he did not think that in the case related it was proved that the symptoms followed from the entrance of air alone. If a large volume of soda water were taken into the stomach no such sudden symptoms followed, and in other cases, accompanied by the escape of gas into the peritoneum, no such shock was produced. He thought that after suture some fluid other than milk should be used to test the soundness of the suturing, for milk might be anything but an innocuous fluid. In one case he operated upon a hydronephrosis and made an aseptic fistula in the loin. He was anxious to discover whether fluid passed down the ureter on this side into the bladder, and so he allowed some milk to trickle from the loin sinus down the ureter into the bladder. It set up a most violent cystitis and inflammation of the pelvis of the kidney.—Mr. WALLIS said that the man was not collapsed at first, the history was erratic, and the symptoms indefinite. When water was injected into the bladder it returned forcibly with only a small amount of blood, and he thought that the slight diminution in volume might be due to inaccuracy in measurement. The air test was most striking, and gave rise to absolute symptoms at once, such as would be likely to be produced by a very sudden alteration of abdominal tension. He thought from this experience it would be better to inject the air after an anæsthetic had been administered. He had seen milk injected over and over again into the bladder in cases of vesico-vaginal fistula without producing any distressing symptoms.—Mr. SHEILD remarked that the diagnosis was always the difficulty in these cases, and the facility in diagnosis appeared to be in direct proportion to the size of the rent. In one case which he saw while house surgeon at Addenbrooke's Hospital the history and the symptoms of ruptured bladder were quite clear, but yet when large quantities of water were injected the bladder formed a distinct rounded tumour. Furthermore, the fluid injected was all returned per urethram and was blood-stained. In that case no operation was done and the patient got quite well. Some of these cases were probably instances of partial rupture, and others were small rents which on distension of the bladder were closed by pouching of the mucous membrane. Injection of air was a good method of diagnosis, and had been adopted by Senn for suspected intestinal ulceration and for perforation of the intestine from bullets. Senn had used hydrogen gas, which might not be so irritating as air, for no mention was made of collapse. He asked if the sutures penetrated the vesical wall through the mucous membrane; if so, calculi might form.—Mr. BOWLBY said that he had seen calculi which had been formed on the sutures employed in a case of supra-pubic lithotomy. He thought that the escape of air into the peritoneal cavity would, as a rule, cause such symptoms as had been described. A very small quantity of air would cause disappearance of liver dulness, and such disappearance of dulness had been observed a few minutes after perforation in typhoid fever.—Mr. WALSHAM, in reply, said that the object of the paper had been to discuss the inflation test. He thought that the symptoms described were due to the entrance of air, for the signs of shock passed off directly the peritoneum was opened. He had never seen any harm follow the use of milk injected into the bladder. It appeared that the injection of air would be of chief value where the rent was small. He did not pass the sutures into the vesical cavity. The peculiar grating sound produced when the catheter was passed through the rent in the vesical wall into the recto-vesical space was very marked, and he did not think that he had laid sufficient stress on it from a diagnostic point of view.

OBSTETRICAL SOCIETY OF LONDON.

The Development and Normal Structure of the Human Placenta.—Exhibition of Specimens.

A MEETING of this society was held on June 5th, Dr. F. H. CHAMPNEYS, President, being in the chair.

Dr. EDEN read a paper on the Development and Normal Structure of the Human Placenta, which was a short abstract of a communication about to be published in the *Journal of Pathology*. He said the placenta consisted of two series of structures: one developed from the ovum—the foetal placenta; the other developed from the uterus—the maternal placenta. The foetal placenta was developed from the external foetal envelope or chorion. At the end of the second week the chorion was covered with villi, the reflexa had closed over the ovum, and the tips of the villi were loosely embedded in it. The foetal and maternal vessels were thus brought into close relation, and the general arrangement represented a simple type of diffused placenta. The development of the discoidal placenta merely consisted in the specialisation of a part of the chorion. The placental chorion consisted of three sets of structures: (1) a covering of epithelium, (2) a connective tissue stroma, and (3) bloodvessels. The chorionic epithelium consisted of two layers; the superficial layer or trophoblast represented the foetal epiblast and was the more important of the two. By a process of proliferation buds were formed from the trophoblast, which developed into new villi, and the steps of the process were described. The stroma consisted of a delicate reticulum of branching connective tissue corpuscles with numerous leucocytes. The meshes of the stroma formed a system of lymphatic channels which were in communication with the capillaries. The vessels of the villi were very large and numerous, and ran for the most part immediately beneath the epithelium; this was an arrangement favourable to osmosis. The lymphatic system of the stroma could be artificially injected from the capillaries. In uninjected placenta blood was often found in the stroma, so that the villi appeared to be soaked with blood like a sponge. The maternal placenta was developed from the uterine mucosa. The earliest changes were a continuation of those found in menstruation, for the fertilised ovum was engrafted on the mucosa in its active phase. The development of the decidua consisted of three stages. In the first stage extensive hæmorrhages occurred in the decidua, and decidual cells were formed in large numbers from the connective tissue corpuscles. These changes were preparatory, and could be found in all parts of the decidua during the first month. In the second stage the chorionic villi invaded the serotina, and the maternal vessels were opened up, thus establishing a circulation through the intervillous spaces. The invasion of the serotina appeared to be the result of the great activity of the trophoblast layer, and the steps of the process were described. The decidual cells also showed great activity in the absorption of blood effused into the serotina. Large lacunæ were formed by the opening up of neighbouring vascular and glandular channels. The changes characteristic of this stage were found at the growing margin of the placenta up to the last weeks of gestation. The third stage represented the adult stage of the serotina. All active processes had then ceased, and the serotina had undergone some amount of consolidation and repair. The course of the maternal vessels through the serotina and their openings into the inter-villous spaces were described in detail. The inter-villous spaces were, according to Dr. Eden, made up (1) of the space existing primarily between the decidua and the chorion; (2) of spaces formed by destruction of decidual tissue; and (3) of glandular and vascular channels opened up in the same way. The circulation through the inter-villous spaces was not rapid, the outflow being chiefly promoted by the intermittent contractions of the uterus. The giant cells so often described in the serotina were really embedded trophoblastic buds. The foetal and maternal structures of the placenta were firmly bound together by the attachment of numerous villi to the serotina; the changes occurring at the site of attachment were described. Owing to this firm union, separation of the placenta during labour occurred, not between the foetal and maternal layers, but through the loose cavernous layer of the serotina. The paper was illustrated by a large number of lantern slides (photo-micrographs), in which the processes described by Dr. Eden were depicted.

Mr. ALBAN DORAN showed a lantern slide (photo-micrograph) of a Section of Placental Polypus. He proposed to deal with the subject of placental polypi and their relation to malignant disease in a paper.

The following specimens were shown:—

Dr. W. DUNCAN: (1) Large Gangrenous Myoma removed by Hysterectomy; (2) Early Embryo in Amniotic Sac which had been retained in utero eight months; (3) Tubal Mole Pregnancy removed by Abdominal Section; and (4) (for Mr. G. H. JONES) Double Monster (Thoracopagus).

Dr. PLAYFAIR: (1) Ovum in a Sarcomatous Uterus which had been extirpated per vaginam; and (2) Sarcoma of Uterus extirpated per vaginam.

Mr. R. O'CALLAGHAN: Myoma of Uterus removed by Hysterectomy.

Dr. LEWERS: Six Specimens of Cancer of the Cervix Uteri removed by Supra-vaginal Amputation, in which eight years, seven years, five years, five years, three years, and two years respectively had elapsed without recurrence.

Dr. ADDINSELL: Deformed Fœtus.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Exhibition of Cases and Specimens.—Cobra Venom.—Tuberculous Pleurisy.

THE twelfth meeting of this society was held on June 5th, Dr. CLOUSTON, President, being in the chair.

Mr. SHAW MACLAREN showed a Right Kidney removed for Malignant Disease. The tumour was too large to remove between the ilium and ribs, and so it was removed by an anterior incision from the ribs to the groin, with a second incision backwards into the lumbar region. The patient only survived three days, though there was entire absence of shock. There was no peritonitis or suppression of urine. The tumour was a malignant adenoma.—Mr. MacLaren also showed a photograph and microscopic specimen from a case of Malignant Adenoma of the Scalp.

Dr. LEITH showed: (1) the Skeleton from a case of Double Congenital Dislocation of the Hip-joint combined with Rickety Curvatures in the Vertebral Column and Tibiæ; (2) three conditions of Hydronephrosis, in the first of which there was stricture of the urethra; the second showed enormous dilatation of the bladder, marked left hydronephrosis, and hypertrophy of the right kidney; there was no obstruction in the urinary passages; the patient suffered from diabetes mellitus.

Dr. ELDER showed a specimen of a Brain with Hæmorrhage into Broca's Convolution and the part between Broca's Convolution and the Internal Capsule. The part of Broca's convolution affected was the posterior half. The symptoms during life were almost those of bulbar paralysis. There was paralysis of the lower part of the face on the right side, the muscles of the lips, tongue, throat, and those involved in deglutition. The vocal cords were not involved. There was no real motor aphasia.

Dr. ALLAN JAMIESON showed a case of Psoriasis with Peculiar Crateriform Arrangement of the Scales.

Dr. NORMAN WALKER exhibited a case of Eczema and a case of Lupus Erythematosus in an early stage.

Professor FRASER showed Rabbits under the Influence of Cobra Venom. He remarked that he had been struck with the statement, which seemed to be a fact, that snake charmers seemed to be immune to the bites of the most poisonous snakes, and that snakes were immune to the venom of other poisonous snakes. Since 1889 he had been collecting the venom of serpents from India, Africa, Australia, and other parts, especially cobra venom. The experimental work formerly brought forward had been unsatisfactory, though it tended to show that a certain amount of immunity might be produced. In his own experiments he had found it very difficult to immunise animals, more difficult than in the case of diphtheria, for the death-producing qualities of the venom were much greater than that of diphtheria toxin; the minimum quantity killed within a few hours, while in the case of diphtheria it was a matter of several days. He found considerable difficulty, but after a time he succeeded in rendering the animals immune. He had begun by injecting small doses, one-tenth of the minimum lethal dose of the venom at short intervals of two to three days. In about twenty days the dose had been increased to half the minimum lethal

dose; the dosage was gradually increased till, at the end of five months, fifty times the minimum lethal dose could be administered. Two rabbits which had received fifty times the minimum lethal dose were shown. They were in good health and had increased in weight. One animal had received enough cobra venom to kill 320 rabbits of its own weight. Observations with the blood serum of animals immunised to thirty times the minimum lethal dose had been made. He showed a rabbit which had received twice the minimum lethal dose. Thirty minutes afterwards, when toxic symptoms had developed, the antitoxin serum was injected, and the animal almost at once began to recover, and complete recovery took place. In most cases of death in man the fatal issue occurred at a longer period than three hours after the bite, so that probably the individual had not received much more than the minimum lethal dose, and thus the conditions were very favourable to the use of an antidote.

Dr. ALEXANDER JAMES read a paper on Tuberculous Pleurisy. He dwelt on the well-known connexion between pleurisy and tuberculous affections of the lungs, and pointed out how often pleurisy preceded tuberculous phthisis. He described the case of a patient who had been admitted to the infirmary for pleurisy which had lasted two and a half months. There was no tuberculous history in the family. The illness had begun acutely with shivering and pain in the side. Pleurisy with effusion was developed, with breathlessness. As fluid remained in the chest, two and a half months after the commencement of the attack he was sent to the infirmary. The temperature on admission was fluctuating. After some weeks the chest was tapped, 130 oz. being removed by repeated tapplings. No improvement took place. He began to complain of pain in the opposite side. Pleurisy was discovered and effusion rapidly took place. Both sides were tapped repeatedly to relieve dyspnoea. As his condition in the next three months deteriorated the left side was opened and drained, but the patient sank and died. Post mortem the pleura was found very much thickened on both sides; miliary tuberculous nodules were numerous in the lung and pleura; other organs showed tuberculous nodules. Such cases, he remarked, were not uncommon. There had been right-sided pleurisy of a chronic character, followed after some months by pleurisy on the left side, the miliary tuberculous process commencing in the pleural membrane while in a low state of vitality, and spreading to the lungs and other organs. There was no evidence of the tuberculous process having begun in the lung. Cases of pleurisy with a similar course might be met with, but then there was no evidence of tubercle. Thus a man aged forty-seven was admitted to his ward complaining of pleurisy. The family and personal history was good. He had been ill for one and a half months. Effusion was present on the right side, and this was followed by pleurisy and effusion on the left side. Tapping was repeatedly performed, but no improvement took place. He developed catarrhal pneumonia and died, his entire illness having lasted six months. No evidence of tubercle was found post mortem. In these chronic cases no ordinary treatment did good. He advocated the trial of free incision, as it held out the best prospects of a cure. A second plan of treatment might be to aspirate part of the fluid and inject the chest with an aseptic fluid which would increase the absorption from the pleura. Drainage held out the best prospects.—Dr. Affleck, Dr. Philip, Dr. Leith and Mr. Gilles took part in the discussion which followed.

Mr. WALLACE's paper on Some Notes on Hæmaturin Tumours of the Bladder and the Treatment of Enlarged Prostate was taken as read.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Imperforate Anus necessitating Colotomy.—Exhibition of Specimens.

A MEETING of this section was held on May 10th, Dr. R. D. PURSER, the President, being in the chair.

Dr. KIDD described the case of an infant three days old whose bowels had not acted since birth, although it had passed urine. An endeavour was then made to introduce a small soap suppository, but this failed. On examination it

was found that the abdomen was distended and that the anus was normal for a distance of about half an inch, but that even a fine probe could not be passed any further. Unavailing attempts were then made to reach the cul-de-sac of the bowel from the anus. There did not exist any chord-like structure that might serve as a guide to the bowel, nor when separating the tissues (although, as was seen by the specimen, the top of the little finger was within about one-sixteenth of an inch of the cul-de-sac) was there ever felt any impulse when the child cried, nor was there any indication from the sense of touch that the cul-de-sac of the intestine was so near. The tissues were divided with a fine tenotome and scissors for some distance backwards from the anus towards the tip of the coccyx, afterwards exploring as carefully as possible with the tip of the little finger. There is very little room between the rami of the ischia in a new-born infant when a finger, even the smallest, is in the anus. The advice given by most authorities to keep close to the anterior surface of the coccyx was followed. A spring wire nasal speculum of small size was used in the hope of getting a view of the tissues which were being dissected, but no success was obtained. Amussat has recommended the removal of the coccyx as a step of the operation, it allows so much more room. On looking at the specimens now exhibited this is quite evident, and it is a matter of regret that recourse was not had to this procedure. Failing to reach the bowel, the wound was well powdered with boracic acid and dressed with a little iodoform gauze and gauze tissue. On the following day another attempt was made to reach the rectum from the anus, but with no more success than the first. No cutting was done with the knife where the part could not be reached with the finger tip. All endeavours being futile, left inguinal colotomy was performed, but the child only survived six days, dying when it was ten days old. The colotomy relieved it, but death ensued from exhaustion. At the necropsy there was no evidence of any peritonitis. A frozen section of the parts was exhibited, the points of interest in which are: (1) the extreme beauty of the specimen, showing so clearly as it did the exact relation of all the parts—notably, the height to which the empty bladder extends above the level of the uterus; (2) the absence of any chord-like structure that would act as a guide to the termination of the rectal cul-de-sac; (3) the very small amount of oozing from the anal wound after two attempts had been made to reach the bowel; (4) absence of any evidence of peritonitis after death; (5) although the tip of the little finger could be got within one-sixteenth of an inch of the rectal cul-de-sac there was no evidence from bulging or from any impulse conveyed by the child crying that the bowel was so close; and (6) considering the distance of the bowel from the anus, could the rectum have been successfully freed and drawn down so as to stitch it to the anus?—Dr. GLENN said the Academy were very grateful for the opportunity of inspecting the frozen section. In two cases which he had seen operated on in the Rotunda one had recovered, but in the other the rectum could not be found. He would remove the coccyx if he had a case similar to Dr. Kidd's, and he would prefer a Littre's operation to a loin operation, the advantage of a Littre's operation being that after the bowel was opened it was possible to wait till the child got stronger, and then, by passing down a bougie, it could be cut on through the anus. If the rectum was brought down and stitched to the anus there was great trouble in keeping it dilated afterwards.—Dr. SMITH, when assistant-master at the Rotunda, had operated on a case and had succeeded in opening into the rectum. He stitched the rectum to the anus. The child only lived a few days. Except when there was only a simple membrane between the rectum and anus he had not seen any cases operated on which had recovered.

Dr. ALFRED SMITH showed an Ovarian Cystoma removed from a married woman aged twenty-nine years. The diagnosis caused considerable difficulty. In September, 1894, the patient had a severe pain in her right side in the neighbourhood of the umbilicus, and shortly afterwards felt a tumour in this region. She stated that it underwent great alterations in size. The sudden diminution was followed by an increased quantity of urine. Examination revealed a tumour the size of a small foetal head, freely movable in every direction, capable of being easily pushed up under the ribs, and distinctly reniform, the hilum being well marked. Drawing down the uterus to the full extent and pushing up the tumour under the ribs did not stretch the pedicle so as to convey impulse. Operation revealed a multilocular ovarian

tumour having an extremely long pedicle and a shape distinctly like that of a kidney. One of the cysts was perforated by a well defined punched-out hole, through which the cyst contents escaped into the peritoneal cavity. This hole explained the sudden diminution of the size of the tumour. The recovery was rapid.—Dr. KIDD asked whether any peritonitis was present. According to Dr. Smith's theory the tumour emptied itself through the opening into the peritoneum. The fluid in most multilocular cysts was irritating to the peritoneum.—Dr. SMYLY said the tumour had a close similarity to one caused by hydronephrosis, both in its shape and in its becoming larger at times. Referring to the escape of the fluid he said that, if the cyst was an ordinary proliferous glandular cyst, it would contain pseudo-mucin, which is not easily absorbed by the peritoneum, and which would, therefore, have been found in the peritoneum. On the other hand, if it was a papillomatous cyst the prognosis was very bad.—Dr. SMITH, replying, said there was no evidence of peritonitis except that there was a fair amount of ascites present. He hoped that it was not a papillomatous cyst.

Dr. GLENN exhibited a Uterus removed by Vaginal Hysterectomy for Epithelioma of the cavity.—Dr. SMYLY thought that in cases of cancer of the body not involving the cervix removal by ligature was the best method, as the uterus had not then to be opened. The uterus might, however, be too large to remove entire.

SECTION OF PATHOLOGY.

Chronic Articular Rheumatism.—Fracture of the Fibula.—Exhibition of Specimens.

A meeting of this section was held on May 17th, the PRESIDENT being in the chair.

Dr. BENNETT read a paper upon the Limitation of Chronic Articular Rheumatism. Referring to the extraordinary polish shown by the pisiform bone in one of the specimens, he said that where there was the least range of movement there was always the greatest amount of polish.

Dr. E. H. BENNETT gave the details of three cases of Fracture of the Fibula, with Dislocation of the Ankle-joint, which had united with great deformity; he had, however, been able in great measure to rectify this by extension and manipulation. The cases had been left unreduced for periods respectively of a month, six weeks, and, lastly, three months. He pointed out the error of regarding Pott's fracture as the commonest injury of the fibula found associated with dislocation of the ankle. He showed by the series of fractures collected in the museum of Trinity College and by his own clinical experience that the oblique fracture of the external malleolus, caused by traction acting through the external lateral ligament, is of much more frequent occurrence than the classical Pott's fracture.

Mr. H. GRAY CROLY and Mr. GRAVES showed an Aneurysm of the Abdominal Aorta which had commenced posterior to the cœliac axis. The sac had become firmly adherent to the lumbar vertebrae, and had also firm adhesions with the left side of the diaphragm and the left psoas muscle. There had been no symptoms of aneurysm during life, no pulsation, and no pain in the back, although the anterior surfaces of the first dorsal and first and second lumbar vertebrae were eroded, pain in the region of the left kidney alone being complained of. The kidney was displaced downwards by the aneurysm. Death took place suddenly from rupture through the diaphragm into the left thorax.—Dr. McWEENEY wished to know how an aneurysm situated behind the cœliac axis ruptured into the left pleural cavity. A short time ago he saw a case in which an aneurysm situated in the middle of the dorsal region of the aorta had ruptured into the substance of the lung and not into the pleural cavity.—Dr. GRAVES, in reply, said that the aneurysm had become glued to the psoas muscle, and had eroded it and pushed it up, and that it had then burst through the diaphragm.

Dr. J. O'CARROLL exhibited the Brain and Spinal Cord of a case of Syringomyelia.—Dr. McWEENEY said the case was absolutely unique in his experience. The only part that he had as yet been able to make sections of was in the cervical region. The section was stained by Pal's method. The central canal was lined by the usual columnar epithelial cells. At each lateral aspect there was a cleft or aperture through which the central canal communicated with two wing-shaped cavities, which extended back to the exit of the posterior nerve roots. There were then two things which had occurred. One a dilatation of the pre-existing central

canal, and the second a channeling out of the grey matter on each side of the cord. There was no evidence of neuroglia either of new formation or of embryonic origin. The cavity in the grey matter was bounded by inspissated grey matter. The dilatation of the cavities of the central nervous system must have been forming many years before the spinal cord symptoms appeared. Then it suddenly opened out the grey matter on each side of the cord, forming there two large cleft-like cavities, extending through its whole length. In the cervical region there was a small aperture between the central canal and the canal in the grey matter. This aperture gradually widened out, so that in the dorsal region there was no division between the two canals. The sclerosis was chiefly situated in the white matter of the posterior columns.

SECTION OF SURGERY.

Injuries involving the Articulations of the Metacarpal Bone of the Thumb.

A meeting of this section was held on May 24th, the President, Mr. W. THORNLEY STOKES, being in the chair.

Dr. E. H. BENNETT, speaking on the subject of Dislocation of the Metacarpal Phalanx of the Thumb forwards, exhibited photographs of a recent specimen of unreduced dislocation, and casts of several others, the histories of which prove that this dislocation frequently remains irreducible, even while still recent—a fact the cause of which was as yet not ascertained. He next projected on the screen with the lantern representations of the lateral dislocation of the metacarpo-phalangeal articulation outwards, published by Beasel Hagen, which is the only example of this lesion recorded. He then exhibited photographs of a lateral dislocation of the joint inward, taken from the cast of the limb previously to dissection. This is the first record of an internal dislocation of the joint. In this hand the metacarpal bone of the thumb was at its base completely dislocated backward, presenting a deformity which Dr. Bennett contrasted with the deformity produced by fracture of the base of the metacarpal bone of the thumb, of which he exhibited a large number of photographs, in proof of his assertion that this fracture is a very common injury.—The PRESIDENT said the paper was exhaustive, and, to a very great extent, original.—Mr. MYLES had only met with one case of Hey's dislocation in the living. After some trouble he had reduced it by exaggerating the deformity, the patient being under chloroform. He did not comprehend how the sesamoid bones got between the head of the metacarpal and the base of the phalanx, with their articular surfaces turned towards the latter.—Mr. HEUSTON said that five months after the occurrence of a compound dislocation of the carpo-metacarpal joint of the thumb, when the dislocation was still present, he dissected down on the articulation, from the internal aspect, and found that the sesamoid bones had got between the two parts. He dissected them out, and was then able to reduce the dislocation. He did not see which way the articular surfaces of the sesamoid bones were turned.

THE CONVERSAZIONE of the Society of Arts is fixed to take place at the South Kensington Museum on Wednesday, June 19th. The reception will be held by Major-General Sir John Donnelly, K.C.B., Chairman, and the members of the council of the Society; and promenade concerts, a glee and madrigal concert, and a vocal and instrumental concert will be given at intervals during the evening.

GORDON'S NATIONAL MEMORIAL.—The annual general meeting in connexion with the Gordon Boys' Home was held on Monday last at the Mansion House, under the presidency of Sir Reginald Hanson. The annual report showed that the number of boys in the Home during the year ending March 31st last was 340. It had been necessary to send some of those admitted away, while a few wild Arabs had absconded. Of the remainder some had enlisted in the army and navy, others had been found situations in civil occupations, and three had been helped to emigrate. The total expenditure for the year had exceeded the income by £4423, £2013 of which deficiency had been made good from the donations received during the year. A most deserving charity, instituted in appropriate honour of one of our most popular, and deservedly popular, national heroes, should not be thus left to depend on its capital for its current expenses.

Reviews and Notices of Books.

Traitement des Fractures par le Massage et la Mobilisation.
Par le Dr. LUCAS-CHAMPIONNIÈRE, Chirurgien de l'Hôpital
Beaujon. Paris: Rueff et Cie. Pp. 564. 1895.

OF recent years many departments of surgery have advanced with enormous strides, but in the treatment of fractures of bones very little progress has been made. Long ago it was laid down as a rule admitting of practically no exceptions that absolute immobility was the essential element in the treatment of fractures, and the changes made were chiefly attempts to attain to the perfection of immobility. But of late years there have been a few who have urged that the harmful results of complete immobilisation of a fractured limb more than counterbalance the advantages claimed for it, and the work before us is the fullest account hitherto published of the treatment of fractures with the minimum of fixation. Dr. Championnière tells us that in 1867 he saw a case of unrecognised fracture of the radius which had united without any impairment of the function of the limb, the patient having used the hand from the time of the accident. This case induced him to attempt the treatment without fixation of all fractures of the radius which came under his observation. Later in 1874 he applied the same principles to fractures involving joints, but it was not until 1884 that his treatment assumed its present form.

The book commences with a historical introduction, and a chapter is devoted to proving that the results of fixation are far from being all that could be desired; thus, although fixation may relieve the pain at the time, yet the pain felt on attempting to use the limb subsequently is often very great, and, though six weeks after a fracture of the leg a patient may be able to get about on it, yet it is much later before he can use it as freely as he could before the accident. The author then proceeds to lay down the principles which should, in his opinion, govern the treatment of fractures. He urges that some degree of mobility at the seat of fracture is essential for the formation of sufficient callus, and that massage, judiciously applied, assists the consolidation of the bone and preserves the suppleness of the joints, muscles, and tendons in the neighbourhood of the fracture. The author lays great stress on the painlessness of the process of massage over the seat of fracture, and even claims that the pain which has previously been present is relieved. He then describes four ways in which massage may be applied. In the first the massage is commenced immediately after the accident and regularly continued. The cases suitable for this are those fractures which are not liable to displacement, as fractures of the radius and the fibula; it is also to be used in fractures near joints, as in fractures of the neck of the humerus and certain fractures of the condyles of the femur. In the second class of cases immediate massage is employed, followed by the application of a splint. This may be used for the fractures already mentioned when the tendency to displacement is great, and also for fractures just above the malleoli. By the third method an immobilising apparatus is applied, and removed at the end of two or three days, when massage is performed and the splint is reapplied, this procedure being repeated every day. This can only be done for fractures where the displacement has a medium tendency to recur, as in the leg and the arm, especially the forearm. In the last class of cases complete immobilisation is employed, and after the commencement of consolidation, massage is used. This applies to cases where the mobility of the fragments is very great; by the fixation at first a mass of callus rapidly forms, sufficient to allow the splint to be withdrawn for the purpose of performing massage, and the splint may or may

not be replaced after the massage, according to the mobility of the fragments. In this class are included fractures of the upper end of the humerus and of the lower end of the same bone. Dr. Championnière acknowledges that there are certain fractures for which massage cannot be employed, and for some others massage is possible, but difficult. The contraindications for massage are two in number—firstly, when the mobility of the fragments is very great and threatens to lead to permanent and marked deformity (though in some of these it may be usefully employed when partial consolidation has occurred), and, secondly, when the fracture is compound and the wound is in a situation to interfere with the massage. It is advised that each application of massage should be at least a quarter of an hour in duration, but that half an hour is better, except just at first.

Many chapters are devoted to the consideration of the various fractures in detail, and those forms of massage are described which are applicable to each. Numerous explanatory illustrations are given of the manipulations to be employed. As to the results the author claims that the full function of the limb is obtained as soon as the bone is firm enough to be used. The method advocated in this volume deserves at least a careful trial at the hands of the surgeons of this country; and though its application may prove to be somewhat more restricted than its inventor claims, yet probably its employment in some cases will lead to results not to be obtained by the methods hitherto in use.

A Manual of Gynecological Practice for Students and Practitioners. By Dr. A. DÜHRSEN, Privat-docent in Midwifery and Gynecology in the University of Berlin. Translated and edited from the fourth German edition by J. W. TAYLOR, F.R.C.S. Eng., and FREDERICK EDGE, M.D. Lond. With 120 illustrations. London: H. K. Lewis, 1895.

THE translators have done good service by rendering Dr. Dührsen's excellent little text-book available for the general English reader. Much of it is, as they say, coloured by the individuality of modern German thought and method. We agree with them that this is rather an advantage than not, and that it gives a freshness to subjects which are otherwise somewhat well-worn. The translators have added footnotes at various parts of the work where the author's views seemed to them to require amplification or qualification. Among the special features of the book may be noticed the description of Dührsen's vaginal operation for fixation of the uterus. In this operation, by which it is claimed that retroflexion may be completely and permanently cured without any danger, the peritoneal cavity is opened between the bladder and the uterus, and the body of the uterus is sutured to the anterior vaginal wall. Another operation evidently in favour with the author is vaginal coliotomy; the vesico-uterine pouch of the peritoneum is opened, not Douglas's pouch, as would perhaps have been more generally expected. Although it is claimed that after the operation there is no more disturbance than after a curetting, the sphere of the operation would seem to be a very limited one. There are two points in regard to pessaries which seem to us of general interest. First, as regards the treatment of retroflexion by pessaries, the author is of opinion that a permanent cure may be obtained in varying periods of time; that is to say, that the uterus will then remain in its normal position without a pessary. The second point concerns the treatment of prolapse by pessaries. Dr. Dührsen considers that a true prolapse can only be cured by operative means and not by pessaries. Although these may keep the prolapse up, it is only by stretching the vagina, so that in the end they make matters worse. He concludes, therefore, that the use of pessaries in the treatment of prolapse is to be rejected as

wrong in principle. We do not think that in cases of prolapse where the vaginal portion comes outside the vulva it is quite correct to say, as is stated in the text, that the fundus uteri retains its normal elevation; nor, on the other hand, do we agree with the footnote made by the translators on this point, in which they say that in most of the cases in question the sound will not pass beyond the usual distance. Generally the sound in such cases passes four or five inches. We see that the translators consider that the liquid extract of viburnum prunifolium is of all drugs supposed to have any influence on chronic oöphoritis, the most reliable. The translators recommend for obtaining and keeping up anæsthesia a mixture of two parts of ether with one of chloroform, given with Clover's Inhaler without using an air-bag. There is an excellent section on the disinfection of instruments and appliances, and, indeed, the whole work will amply repay perusal by all interested in the subjects of which it treats.

Manual of Practical Morbid Anatomy. By H. D. ROLLESTON, M.A., M.D., F.R.C.P., Fellow of St. John's College, Cambridge, Assistant Physician and Lecturer on Pathology at St. George's Hospital, and A. A. KANTHACK, M.D., M.R.C.P., Lecturer on Pathology at St. Bartholomew's Hospital. Cambridge: University Press. 1894.

THIS small and beautifully printed volume is one of the biological series of the Cambridge natural science manuals, and is intended to serve as a handbook for the post-mortem room, and it does so most completely. Its objects are two: (1) to indicate the incisions and the most convenient way of examining the organs of the body, and (2) to point out the morbid changes to be looked for, thus making it a valuable manual of morbid anatomy, and not a mere post-mortem guide. A systematic method of examination has been described paragraph by paragraph, and, in special cases, modifications are also introduced. The normal appearances of organs, the common variations, and the effects of post-mortem change are carefully pointed out. But besides the ordinary methods of a post-mortem examination, in confirmation or otherwise, of the diagnosis of the physician or surgeon, the higher pathological uses of the necropsy are carefully kept in the foreground of the work. Details of preparations for further microscopical and bacteriological observations are most carefully given, and in the introduction directions are also added for the temporary or permanent preservation of specimens of morbid anatomy. These are taken almost literally from a letter of Mr. E. W. Willett, curator of the Museum of St. Bartholomew's Hospital, published in THE LANCET of Nov. 25th, 1893. The first chapter in the work is devoted to general matters, and the signs of death, rigor mortis, hypostatic congestion, the examination of the skin, the peculiarities of a medico-legal examination, the nature and direction of wounds, and the points to be specially noted in a necropsy on a newly-born infant are briefly but clearly described. The other chapters deal successively with the preliminary examination of the abdomen, the examination of the thorax, the detailed examination of the abdominal viscera, the examination of the kidneys and pelvic viscera, the head (including the brain, eye, ear, and nose), the spine and spinal cord, the joints and bones, and lastly the female breasts. One point of detail in which we differ from the authors is with regard to the removal of the small and large intestines during the preliminary examination of the abdomen before the thorax is opened. We should certainly leave them *in situ* until we had completed the examination of the thorax, and examine them in anatomical order with the other abdominal viscera. Again, we should not cut across the duodenum but the commencement of the jejunum, and should always apply a double ligature and cut the gut between, for no one can ever be sure at this stage that the preservation of the contents of

the stomach and duodenum may not be required for further examination. These, however, are points of but minor importance, and we would add that in our opinion it should be a compulsory part of every student's medical education for him to have made some post-mortem examinations under the supervision of a teacher. If these were carried out in the thorough and orderly manner laid down in this handbook this experience would be of the utmost service to him in his after career, whether as a practitioner or teacher.

LIBRARY TABLE.

Comfort in the Home. By M. J. LOFTIE. Leadenhall Press. 1895.—The progress of medical science is universally allowed to be tending more towards the prevention of diseases than to the curing of them when once they are established. Some sage once said it was worry, and not work, that killed; and in the unpretending little book before us we find various plain directions for the prevention of worries in the home—not, indeed, the worries which arise from babies or "incompatibility of temper," but matters like lamps, fires, and dust-bins. Nothing is more annoying than a lamp which smokes, and how few servants know how to "do" a lamp properly. If they will look at Mrs. M. J. Loftie's plain rules they will find out. We rather disagree with the author's direction, "Blow lamps out, don't turn them down." In certain forms of cheap lamp to blow down the chimney means death; and in those of better construction the flame should be turned low and then blown out by a sharp puff *across* the chimney-top. This, however, is the only flaw we have been able to find in a really admirable little work.

Dental Microscopy. By A. HOPEWELL SMITH. Pp. 119. With Eight Lithograph Plates from the author's original drawings. London: The Dental Manufacturing Company, 6 to 10, Lexington-street. Philadelphia: The S. S. White Dental Manufacturing Company, Chesnut-street.—This is an excellent little volume. The present standard works on histology give hardly sufficient data with regard to the preparation of good specimens of the dental tissues, but this want will be no longer felt, for Mr. Hopewell Smith's book contains all the information that can possibly be needed. The subject matter is divided into eight chapters, the first of which deals with the necessary apparatus required; the second, third, and fourth with the preparation of the hard and soft tissues; the fifth, sixth, and seventh with imbedding, staining, and injecting; and the last with photo-micrography. Preceding the subject matter are eight lithographed plates illustrative of dental histology. These are worthy of much praise, the drawings being very fine and conveying a truthful impression of the actual appearance of specimens when viewed through the microscope. Altogether this book will form a correct and concise guide to those who work, or intend to work, in the much-neglected field of dental microscopy.

Report of the Devonshire Hospital and Buxton Bath Charity.—This report, which includes the period from May 1st, 1894, to April 30th, 1895, shows that during the year 2610 in-patients have been under treatment in the institution. This number is fewer by 141 than was recorded at the last subscribers' meeting. More than the whole of this lessened number applies exclusively to the first three months of the present year, as the number under treatment during 1894 was 97 in advance of the year preceding, and this smaller number was therefore due to the exceptional severity of the weather during the period. The results of the residence and treatment were not less satisfactory than usual. Of the 2610 patients under treatment 2279 were discharged as "improved," 109 as "no better," 7 by "own request," 5 were found to be "unfit cases" for the hospital, 2 were "infected with vermin," two were "transferred" to be out-patients, one

was found to be "mentally affected," one was discharged for "breach of rules," four "died" during their stay in the hospital, six left "without report," and 194 remained "on the books" on April 30th. The four deaths serve to impress the fact that many of the cases are of seriously urgent character, and also to demonstrate the nature of the work of the hospital. By means of a postcard, given to every patient on leaving the hospital, and returned after an interval of six weeks, more than two-thirds are stated to have been benefited, and seven of these to have died within this short period after discharge. It may be noticed that no fewer than 454 of the cases of rheumatic character were found to be complicated with morbid conditions of the heart, and that 2279 of the cases were of a rheumatic or gouty nature.

Analytical Records FROM THE LANCET LABORATORY.

BINIODIDE OF MERCURY AND OTHER SOAPS. (EDWARD COOK AND CO., SOAP WORKS, BOW.)

AMONGST the number of excellent medicated as well as toilet soaps manufactured by this firm the antiseptic soap made with the periodide of mercury stands first in point of interest to the profession. The powerfully antiseptic action of mercuric iodide (HgI_2) is well known, and has been made use of with very good results in parasitic and other diseases, and the convenience of being able to employ it in the comparatively harmless form of soap is obvious. This is done by first dissolving mercuric iodide in potassic iodide, forming a double salt, which is none the less antiseptically powerful than the pure metallic iodide, while with soap it is perfectly compatible and quite stable. Excellent results are recorded of its application in skin diseases, eczema, ringworm, &c. The biniodide soap is prepared in two forms—the first for ordinary usage, and the second (a well-dried soap) for toilet purposes. From its composition it should be a very effectual antiseptic agent, and of peculiar service where antiseptic treatment is indicated. We have examined also two specimens of carbolated soaps—one intended for ordinary purposes and the other of a superior kind and adapted for the toilet. Lastly, the specimen of pure toilet soap, known as "super-fatted Riviera soap," leaves little to be desired in regard to its composition, since it contains a minimum of moisture (5 per cent. only) and gives no indication of free alkali; on the contrary, it contains (as its name implies) a slight excess of fats. It is, therefore, free from those qualities present in carelessly-made soaps which are injurious to delicate skins.

RECENT TABLOIDS.

(BURROUGHS, WELLCOME, & CO., SNOW-HILL-BUILDINGS, E.C.)

"Residuam Rubrum Tabloids" consist practically, as our examination by the spectroscope of an acidulated and alcoholic solution shows, of the hæmatin of bullock's blood, which is, of course, a natural organic iron compound, and therefore one which is likely to be readily appropriated. "Thymus Gland Tabloids" are obviously convenient for use in all lymphatic conditions, and, as recent experience has shown, in some forms of pernicious anemia and leucocythemia. "Dried Sulphate of Iron Tabloids" are supplied for the treatment of anemia, the iron being more permanent in this form than in many other salts. On the assumption that "zymines" or the pancreatic ferments when taken by the mouth are digested and destroyed by the gastric fluids, tabloids coated with keratin containing these ferments are prepared. Their passage unimpaired into the duodenum and intestinal tract is thus ensured. A powerful

antiseptic and germicidal compound is represented in zinc permanganate, which in tabloid form may be readily used for the preparation of a solution for injection, as in gleet, or for gargling the throat. One of the most satisfactory features of the tabloid (omitting the specially coated tabloids) is the surprising and ready way in which it first swells up when placed in water and then collapses into fine powder, so that the employment of the drug in the best possible physical form is inevitable.

VARIOUS TEAS GROWN AT HIGH LEVELS.

We have recently received a number of samples of tea forwarded by Mr. Feltwell of Tolcarne, Chiswick, which are said to illustrate that the greater the elevation at which the tea plant is grown the smaller is the amount of astringent matter developed in the leaf, although it is further stated that at the same time no practical depreciation in regard to the refreshing qualities and alkaloidal constituents of the plant takes place. These teas are said to differ, therefore, in the important respect that they contain much less tannin than the bulk of teas which, on the contrary, are grown comparatively quickly under the influence of the greater warmth of lower elevations. So far as regards the character and taste of the infusions yielded by these high grown teas we found distinct evidence that to some extent this is the case; there is a marked absence of roughness on the palate, the taste is smooth and delicate, whilst it lacks little of the peculiar aromatic character of ordinary teas of excellent quality. Some analyses we made lend further support to this view, since in the accompanying table it will readily be seen that the five minutes' infusion of the high-grown teas—using the same amount of tea in every case—contains a goodly proportion of caffeine (nearly as much, in fact, as in the powerful variety of tea placed side by side in the table), but a notably less proportion of

COMPOSITION IN GRAINS OF HALF A PINT OF CLEAR TEA

tannin. Even a thirty minutes' infusion of the high-grown teas (Table II.) is found to contain less tannin than a five minutes' infusion only of strong Indian or low-grown tea. We have obtained evidence also which shows that there is a distinct increase in the amount of those essential oils which largely determine the agreeable character of tea. There would appear to be, therefore, a distinct dietetic advantage

gained by cultivating the plant on high elevations, where it grows slowly and where it never attains anything like the height and proportion of the plant grown on lower, warmer, and probably moister levels. Thus, to take one example, at Darjeeling, 7000 feet above sea level, the yield is said to be but 200 to 300 lb. per acre, while on the plains of Assam, where the level is only 100 to 500 feet above the sea, it averages from 800 to 1200 lb. per acre. The former teas, however, are moderate in price, and there is considerable interest attaching to the fact, we think, that we have been able to confirm by our own analyses and examination the important dietetic advantage claimed for them, which is that while they do not lack the refreshing qualities of tea as regards flavour and substance, yet they are destitute of that harshness which in powerful teas is ascribed to a preponderance of astringent substances.

STOUT.

(WHITTHREAD & CO., LIMITED, 277, GRAY'S-INN-ROAD, E.C.)

This is a moderately priced and genuine malt liquor, containing 6.43 per cent. of absolute alcohol by weight and 8.01 per cent. by volume; malt extractives, 7.46 per cent.; nitrogenous matters, 0.75 per cent.; and mineral matter, 0.29 per cent. It is free from undue acidity, and, as the above analysis shows, contains to a satisfactory degree those additional nourishing properties which beer, when made with burnt malt, is well known to possess. Its flavour is ripe but mellow.

PREPARED SOUPS.

(LONDON AGENCY: A. CHADWICK, 7, CARLTON-STREET, REGENT-STREET, S.W.)

A very satisfactory feature of these preparations is that, in spite of being "tinned," they yield a highly nourishing liquor which possesses all the characteristics of fresh soup. Two kinds were submitted to us, respectively called "turtle for invalids" and "beche-de-mer soup," the latter being made from the fresh test fish, which has afforded a source of food much prized by the mandarins and wealthy Chinese for centuries. The soups were quite free from objectionable preservatives, and we could trace no injurious metals. They are excellent and satisfactory substitutes when the material cannot be easily or freshly procured.

New Inventions.

SOUTHALL'S NEW SANITARY TOWEL.

THE sanitary towel of this firm, as originally devised, has been a great convenience to women of all classes as a cleanly and economical method of dealing with catamenial troubles. It consisted of a pad of absorbent cotton-wool enclosed in a gauze covering, with a thin layer of non-absorbent cotton-wool as a backing. The contrivance was in every way superior to the ordinary diaper, being more absorbent, comfortable, and cleanly, while it was offered to the public at the cost of the washing of a diaper—viz., one penny. But it was admitted that inconvenience frequently arose in the use of that sanitary towel in consequence of the area of the discharge contracting as the discharges advanced in the pad. The viscous nature of the catamenia was answerable for this failure, which in some cases, where the discharge was copious, led to serious discomfort as well as to injury of the clothes by the arrest of the absorption. The manufacturers are now making the towel in a modified form by which the absorbent qualities are enhanced. A pad is constructed of alternating layers of absorbent cotton-wool and gauze, and it has been found that when the discharge has passed through a thin stratum of absorbent cotton-wool its area, which in its passage through the wool had been gradually contracted, immediately upon coming in contact with the gauze spread laterally and, as it were, made a fresh start of larger area in entering the next layer of cotton-wool, when the process of contracting and spreading was repeated. In this way the tendency in the flow of the discharge to contract its area is counterbalanced, and the inconvenience of

imperfect absorption—dammed-up discharge with consequent roughened edges of the pad and perhaps overflow soiling of the clothes—is remedied. The improved "towels," like the original "towels," are, of course, intended to be burnt after use, and are sold at one penny each.

THE "HOLDFAST" ENEMA SYRINGE, WITH ANCHOR END.

WE have received from Messrs. W. H. Bailey and Son, 38, Oxford-street, a specimen of their new enema syringe. There are two points to be noticed about this instrument: first, it is entirely free from metal; and, secondly, the end which is placed in the solution to be injected is fashioned on the principle of the toy known as a sucker, so that it adheres to the basin, and thus the annoyance so common with the older forms of syringe of either having to hold the end under water or of seeing it slip out is entirely done away with.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the committee of the Association of Fellows of the Royal College of Surgeons of England was held at 5.30 P.M. on June 5th, at 101, Harley-street, W. Mr. George Pollock, the President, occupied the chair. The minutes of the last meeting of the committee were read and confirmed. A letter from the Secretary of the College was read stating that the President of the College had appointed Monday, the 10th inst., at 4 P.M., for the reception of the proposed deputation from the Association of Fellows, and asking to be furnished with the names of those constituting the deputation and with the special matters which the deputation intended to bring before the committee of the Council. The committee then took into consideration the points of reform to be pressed upon the committee of the Council appointed to receive deputations from the Fellows of the College by the deputation from the Association and the composition of the deputation.

A letter was read from Dr. Ward Cousins accepting the invitation of the committee to stand at the approaching election as a representative of the views of the Association, and the honorary secretary reported that Mr. C. B. Keasley and Mr. Victor Horsley were unable to come forward as candidates. The selection of Mr. A. T. Norton and Dr. J. Ward Cousins as the candidates of the Association was then unanimously confirmed, it being understood that Mr. Willett's re-election should also be supported.

The committee then proceeded to draw up a circular letter to be issued to the Fellows of the College detailing the concessions already gained for the Fellows by the agency of the Association, and the further alterations in the Charters and by-laws which the Association was endeavouring to secure.

A deputation from the Fellows' Association had a conference with a committee of the Council of the College in the council-room of the College on Monday, June 10th, at 4 P.M. The members of the deputation were Mr. George Pollock (President), Mr. A. T. Norton, Mr. Vincent Bell (Rochester), Mr. Victor Horsley, Mr. Herbert Allingham, and Mr. Percy Dunn (honorary secretary). They were received by the President (Mr. Christopher Heath) and Vice-Presidents (Mr. Reginald Harrison and Mr. Willett), Mr. Howse, Mr. Morris, Mr. Rivington, and Mr. Tweedy. Mr. T. Holmes, Mr. Parnell, and others were prevented from attending the deputation, and Mr. Bryant was unable to appear on the committee. The suggestions for the alterations in the Charters and by-laws, which had been previously submitted to the committee and have appeared in our columns, were formally submitted and explained. A long discussion ensued, and at the termination of it the deputation was asked to furnish the committee with a *précis* of their reasons for urging the various proposed changes. This the deputation undertook to do, and the conference, which lasted for nearly two hours, terminated with a vote of thanks from the deputation for the courtesy with which they had been received and the attention with which they had been listened to by the President and the committee.

THE LANCET.

LONDON: SATURDAY, JUNE 15, 1895.

THE fifty-eighth session of the General Medical Council, lasting nine days, came to an end on Thursday, the 6th inst. The discussion of the Midwives Registration Bill may by many be thought to be superfluous, seeing that the principle of it has received the attention of the Council for nearly twenty years. It would be quite within the truth to say that the Council has for that period unanimously accepted the principle of it. The Act of 1886, though it made little difference to midwives, did raise midwifery to the level of medicine and surgery. But the Act of 1886 did something more: it gave direct representation. And until now it can scarcely be said that a Midwives Bill has been discussed in the light of direct representation. That can no longer be said.

The Council has devoted the best part of three days to the subject and, under the strong pressure of a party much opposed to any such legislation, has reconsidered its many resolutions in favour of it. The result is to reaffirm the conviction that something must be done to remove the scandals of midwives' midwifery; but the Council has taken the utmost pains to minimise this something, so that the contemplated midwife shall be, as in the past, a nurse-midwife, and nothing more; that she shall discharge no medical functions and assume no medical airs or titles; and that if she does assume such functions or titles she shall in so doing expose herself to penalties, including removal from the register. The Council has, moreover, suggested that in regard to the form of certificate to be given—and this only by bodies approved by the Midwives Board—the approval of the Midwives Board and the General Medical Council shall be secured. The Council also desired amendment of the absurd provision in Clause 16, requiring the consent of the Attorney-General to prosecutions under the Act, and the substitution of the consent of the Midwives Board or of the local authority. It will thus be seen that the Council has endeavoured to safeguard the profession. There is a very general agreement that public opinion demands some legislation of the sort which was under discussion. They are no friends of the General Medical Council or of the principle of direct representation who would set the Council and the direct representatives of the profession against such a demand. The bulk of the profession recognise that there is a great section of the community who are too poor to be attended at any fees which a registered medical practitioner can take, and yet cannot be treated as if they were paupers. It is inevitable that they should largely be attended by midwives. The least that law can do is to secure that they shall be in a degree "protected" from a class of women who have absolutely no knowledge and very little character; that a class with a little knowledge and some character shall be placed within their reach, whose training shall be sound, if rudimentary, and who shall at least be taught to understand that they are to act only in normal cases

and in subordination to medical men. These are the views which the General Medical Council has affirmed again for the fourth or fifth time. Fortunately the Council enjoys now in a large degree the confidence of the profession. It has in the matter of the certificates of the Obstetrical Society shown its determination to protect the medical profession, as in the recent debate it has shown its anxiety to "protect lying-in women from the incompetent." It is not likely to revert to this subject again for many years. It would scarcely be justified in doing so. Henceforth the responsibility for "Gamps" must rest with the Government and with Parliament. Those who are opposed to any legislation will have to make their influence felt without the help of the Council. It may well restrain them to know that by resisting this modest demand they are preparing the way for an inferior race of quasi-medical practitioners, be they trained nurses of three years' standing or unqualified assistants in the form of man-midwives, whose pretensions will be a far more serious competition to medical practitioners than anything contemplated in the Midwives Bill.

It is an illustration of the serious demand on the Council's time made by such matters as the Midwives Registration Bill and lengthy penal cases that when the time came for a formal discussion of the Final Examinations, based on the reports of the Inspector and Visitor and of the Examination Committee, the subject had to be referred to next session. The only consolation is that the General Medical Council in this way keeps some control over the lines of legislation. It would be very unsatisfactory if such Bills as a Midwives Bill could be passed without the amendments suggested by the Council. Another illustration of the importance of the advising functions of the Council is to be found in its action in regard to the recognition of foreign diplomas. The Government of the Netherlands asked for leave to practise in the United Kingdom for its subjects holding a Netherlands diploma. The Council, through its Education Committee, pointed out to the Lord President of the Privy Council that while the Netherlands Government insisted on an examination in final subjects from those holding British diplomas wishing to practise in the Netherlands it would be wrong to concede the privilege asked. Such action on the part of the Council is of the first importance; and it is no slight testimony to the moderation and impartiality with which in public questions the Council discharges its duties that it should be consulted by the Privy Council. We have before now had occasion to find the General Medical Council not entirely alert to its best method of procedure, and even not alive to its weighty responsibilities—our readers will not desire the occasions to be more precisely instanced; but on the whole we congratulate the members upon the result of their fifty-eighth session's work.

THERE seem many signs that we are witnessing the decay of hypnotism. The stream of hypnotic literature would appear to be gradually subsiding—not, perhaps, before it was time—and the interest in the subject, both public and professional, is evidently on the decline. The claim of hypnotism to take rank, not as a curious psychological phenomenon, but as a recognized branch of therapeutics, is

now pressed with much less insistence and sincerity than was the case a few years ago; and it would seem that history is once more repeating itself, and that the periodic burst of attention and curiosity evoked by the subject has for the present, as on former occasions, spent its force. To readers of THE LANCET such a course of events will be in no way surprising. While admitting that modern hypnotism presented some new developments and refinements, we have always maintained that in essence it was identical with the mesmerism, Braidism, animal magnetism, and electro-biology of former times, and that in due course it would be found to be barren, if not noxious, in the field of medicine. Students of psychology must always be interested in the curious phenomena of hypnotism, but we feel more than well justified in having resisted the intrusion of hypnotic doctrine and practice into the domain of medical science. The dangers of the proposed new departure were evident and grave, its advantages at best problematical, at worst illusory and deceptive. It may not be amiss to recall some of the salient features of a controversy which, we suspect, is nearing its predestined termination.

A cardinal point, *ab initio*, was, Are hypnotic phenomena normal or abnormal, physiological or pathological? It has been alleged that the phenomena were perfectly normal and natural, and some of the apostles of the movement have even gone so far as to assert that more than ordinary strength and balance of mind were necessary to constitute anyone a thoroughly good subject for hypnotism. It was said that the power of sustained concentration of attention was the most essential point in securing the success of the experiments, and that such a power was the very antithesis of hysteria or morbid neurosis. On the other hand, the more general and gradually prevailing opinion has been that the hypnotic trance and all the curious attendant phenomena were of the nature of disease and showed a mind not abnormally strong or even normally sane, but to a more or less extent temporarily off its balance. This latter view is, in our judgment, most in accord with recorded fact and most consistent with theory. The hypnotic subjects who abounded in Paris and Nancy did not seem to most dispassionate observers to be good examples of sane and vigorous intellect. On the contrary, the atmosphere of morbid introspection, display, and more or less charlatanism seemed to cleave to these practised performers and all their curious evolutions. Ordinary experience of life teaches us that one of the most potent forces in human nature is the love of notoriety and the desire to become the centre of interested attention. *Possunt quia posse videntur* is a principle of very wide application. Granted an atmosphere of excited interest and a strong expectancy of certain results on the part of subjects and operators, and the most astonishing effects can easily be produced. Again, if it is of the essence of hypnotism that the subject should yield his will to that of the operator, and more or less merge his personality in that of another individual, we think such a condition much more likely to be associated with mental weakness than with mental strength. We by no means assert that conscious imposture was usual in these experiments, although we believe it had often a considerable share in the results, and we quite admit that hypnosis is a genuine phenomenon—as genuine, for example, as somnambulism; but we believe it to be

essentially morbid, and associated with feebleness of will and unusual impressionability. The most probable theory of its causation has always seemed to us the view that was put forward by HEIDENHAIN and other good physiologists—viz., that the hypnotic trance is the result of an inhibition of some portions of the cerebral substance, the remaining portions acting abnormally and giving an extraordinary response to ordinary stimuli.

The second great controversy had regard to the question, Granting that hypnosis is real and can be evoked according to definite rules, is it capable of being turned to useful account in the field of therapeutics? When we reflect upon the strong claims that were put forward for hypnotism as an anæsthetic, an analgesic, a nerve stimulant, and what not, it must seem not a little surprising that so potent an agent should be allowed to rust in the not over-stocked armoury of treatment. We suspect the marvellous results alleged to have been attained have not well withstood the crucial tests of time and wider experience. There was a stage in the annals of this curious history when even grave organic maladies—e.g., hemiplegia, Bell's paralysis, &c.—were alleged to be submissive to hypnotism. We are not sure that even tumours were not alleged to have vanished on the waving of the magic hypnotic wand. But by degrees one claim only was insisted upon—namely, that hypnotism was a potent remedy for "functional" nervous affections. Every experienced physician knows that these maladies constitute the most illusive of all fields for therapeutic experiment. The victim of functional nerve-disorder not infrequently gets well with any treatment or no treatment. Above all is it clear that any strong impression on the nervous system, whether produced accidentally or by deliberate therapeutic endeavour, frequently results in the cure of such cases. That hypnotism is one way of producing such an impression we fully grant, and its beneficial effect might be freely admitted if there was no reason to suspect that the cure might be worse than the disease. To drive out neurasthenia by inducing the hypnotic state is a procedure fraught with so much peril, both on the moral and the physical side, that it can only be undertaken with grave apprehension. The broken-down nervous systems that form the bulk of neurasthenic cases are bad material for doubtful psychical experiments. Rather should we commend in such cases the old and well-tried methods of treatment by rest, change, fresh air, diet, tonics, modification of unwholesome environment, suitable occupation, and recreation. These methods often succeed, and it can at least be said that their failure does not make the last case of the patient worse than the first.

Hypnotism is undoubtedly worthy of study, but we suspect that more and more it will be handed over to the psychologist, perhaps sometimes to the alienist, and that its interest for the practical physician will steadily wane. Until the evidence of its utility is a hundredfold more conclusive than it at present appears we shall not regret having striven to preserve medical science from identification with doctrines and methods which are tainted with charlatanism.

THE review of the position of the Fellows of the Royal College of Surgeons of England in relation to the Council, which formed the substance of our two preceding articles,

must have impressed our readers with the steady progress which has been made during the last ten years by the movement which commenced in 1884 to secure for the Fellows of the College constitutional privileges on a par with those enjoyed by the Fellows of the other professional Colleges in the United Kingdom. Before 1884 the Council of the Royal College of Surgeons reigned supreme and there was no efficient organisation by which its rights could be challenged. Little interest was evinced in the elections to the Council, which were largely in the hands of the metropolitan Fellows, and too often resulted in the return of the typical hospital surgeon favourable to the maintenance of the existing *régime*. A comparatively small number of votes sufficed to secure a seat upon the Council. Consultation with the Fellows and Members of the College was a rare event; the ideas of the responsibility of the Council to the constituency, of an annual meeting, of allowing the Fellows to vote by means of voting papers *in absentia*, and of calling the Fellows and Members together regularly for consultative purposes were scouted by those whose hands held the reins of management.

It was at length perceived by those most interested in the cause of reform both within the Council and outside that it was only by united efforts and efficient organisation any impression could be made upon the *vis inertia* of the Council. As many thought at the time, and as is now sufficiently obvious, the course of litigation upon which certain Members of the College entered with the Council did for a time exercise a prejudicial effect upon the reform movement. These Members pursued a mistaken policy, and, overrating the strength of their position, endeavoured to win by force that which could only be obtained by diplomacy. Many friends were alienated by the extravagance of their demands, but the moment the pressure of these demands was relaxed by the adverse decision in the Chancery Division the wheels of constitutional progress again began to revolve. The Fellows obtained their separate half-yearly meetings, the Fellows and Members obtained their common room, and the Members were benefited by being able to claim to be called together to discuss any subject on which the Fellows had been consulted. The Council became effectually leavened by the introduction of a strong reforming element, and at the present moment there is but a small remnant of the ancient class of councillors still surviving on the Council.

But the very success which has attended the claims of the Fellows constitutes a source of danger. The foundations have been securely laid and the edifice has been erected, but it has not been crowned or rendered proof against adverse elements. Seeing the goodly structure, the Fellows and Members will be apt to imagine that the battle has been successfully fought and that they may lay aside their arms. They forget that all that has been gained for them rests solely upon resolutions of the Council, which might be rescinded or remain a dead letter if apathy is allowed to follow effort and enthusiasm. The great necessity at the present moment is to secure a new Charter conferring upon the Fellows and Members that substantive position which is their due. Statutory meetings must necessarily be more influential than meetings having no official character. Moreover

a new Charter should provide for the election of the President in the mode which commends itself best to the opinion of the constituency authoritatively obtained, and for that change in the constitution of the Court of Examiners and in the term of office of its members which would bring the College more into line with kindred institutions. It is undoubtedly an anomaly that the members of the Council of the College should be able to elect themselves to posts of profit and emolument as examiners, and scarcely less anomalous that examiners should be elected for five years and the term be renewable without any interval. The members of the Senate of the University of London are not eligible for examinerships, and not even boards of guardians can elect their members to lucrative offices. At the College this anomaly has prevailed from its origin and has been an immense hindrance to the cause of reform. At first the examiners entirely controlled the Council, for all were elected from the Council. Now it is true a certain proportion of the court are, though not necessarily, elected from outside the Council.

The foregoing remarks will show that the work of reform at the College, although it has advanced steadily in the last few years, is still incomplete even in relation to the Fellows of the College. The Fellows should not neglect the opportunity afforded by five vacancies to return candidates prepared to comply with the reasonable requirements of the constituency and to make the College a model of good government, instead of presenting features which would never be sanctioned by the State in the case of any new institution. In another column will be found the names of the intending candidates for the forthcoming election. Many of these are more or less identified with the liberal movement, and some have taken an active part in carrying on the work of collegiate reform. We propose to discuss their respective claims to fill the vacant seats in an early issue.

Annotations.

"Ne quid nimis."

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THIS is the last opportunity we shall have of urging upon our readers the claims of the Metropolitan Hospital Sunday Fund for 1895. Before our next issue the appeal to the public of London will have been made from every pulpit, and to a certain extent the material result of that appeal will have become apparent. It is not our intention to state, or rather to re-state, the grounds upon which we base our belief that contributions to the Metropolitan Hospital Sunday Fund fulfil in every conceivable direction the demands of well-directed charity. From year to year and for many a year we have given the reasons for our unvarying advocacy of the Fund, and by our distribution annually of special supplements setting forth the needs of the hospitals of London have aided to the best of our ability the efforts of the executive. We note that this year our example in this direction has been followed by an institutional journal whose imitation we welcome as a proof of the utility of our many previous issues. We do not intend now even to recapitulate our numerous pronouncements on the Fund, but we may be permitted, at a time when the columns of the lay press have been so repeatedly and pointedly open to

the distressful appeals of more than one of our best known metropolitan institutions, to urge upon our readers the extreme need of support in which the objects of the Fund stand. London, the richest city in the world, is content to allow the institutions which provide for her sick to struggle on from day to day begging and ever begging. The aggregate results of these incessant appeals to charity, let it be conceded, are noble. But it must be remembered that poverty is a cause of sickness, and as it is true that an enormous proportion of the patients at the hospitals can directly or indirectly trace their plight to the exiguity of their circumstances, so it is true that our hospitals, if kept at a perpetually low dead level of poverty, may tend to become inadequate to the stress put upon them. How can they look forward to doing better? How can they plan improvements, inaugurate reforms, classify schemes for placing their affairs upon a sounder financial basis, and tabulate arrangements for more competent organisation against the inroads of sickness in the community, if the time of all concerned in the management is for ever occupied in despairing endeavours to make both ends meet? We have deliberately preferred on this occasion not to set out the manifold claims of the Fund on the attention of our readers—they are summarised in the lucid and eloquent letter from the Lord Mayor which we received as we were going to press—and confine ourselves to saying: To-morrow is Hospital Sunday, give according to your power.

THE SECRETARY OF STATE, THE SOCIETY OF MEMBERS, AND THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

SOME misconception seems to have arisen in certain quarters concerning the attitude of the Secretary of State towards the Council of the College in reference to the recent application of the Council for approval of alterations in some of the by-laws of the College. These by-laws were Section 4, relating to the election and admission of Members of the Council; Section 16, relating to misconduct of Fellows and Members; and Section 25, relating to dental surgery. The amendment of Section 4 was for the purpose of simplifying the mode of distribution and collection of voting papers in accordance with the wishes of many Fellows of the College, and the amendment of Section 25 was for the purpose of increasing the fee for the certificate to practise as a dentist from ten guineas to twenty guineas over and above any stamp duty. The amendment of Section 16, relating to misconduct of Fellows and Members, was, we believe, required because the terms of the existing by-law were not sufficiently precise to enable the Council always to remove from the lists of Fellows and Members members of the profession included in the list who had been judged by the General Medical Council to be guilty of infamous conduct in a professional respect, and it has happened more than once that the Council of the College has not been able to deprive of his diploma a Member or Fellow of the College whose name had been erased from the Medical Register. This anomaly the Council, we understand, wished to rectify, and they proposed a formula for the purpose which received the sanction of the annual general meeting of Fellows and Members and the half-yearly meeting of Fellows in January. As soon as the formula had passed the Council and had been submitted to the Secretary of State, the Society of Members of the College took steps to oppose the proposed changes. The Society objected to further increasing the powers of the Council under the present charters and constitution of the College, alleged a want of confidence in the Council as the sole judge of "disgraceful conduct," because the new by-law might be used to repress actions directed against the present government of the College

which might not be covered by By-law 17, and contended that no change in the by-laws ought to be sanctioned which did not include the amendment of Section 17, a by-law most obnoxious to many of the Members. The objections of the Society of Members were forwarded, with the sanction of the Society, to the Council, who drew up a reply, which was sent to the Secretary of State in April. At the Council meeting, held on May 9th, the reply of the Home Secretary was read to the meeting. Mr. Asquith thought there might be some objection to the proposed wording of the paragraphs of the amended By-law 16, on the ground of the wide and indefinite character of their provisions, and suggested that the objects the Council had in view could be attained by means of a by-law in terms similar to those of Section 29 of the Medical Act of 1858, and requested the Council to consider the matter with a view to amending their proposals accordingly. To the other proposed changes Mr. Asquith did not propose to raise any objection. After hearing the letter read, the Council referred it to the President and Vice-Presidents to take such steps in reference to Section 16 of the by-laws as they might deem expedient after consultation with the legal advisers of the College. The result was, we are informed, that the amended by-law was re-worded and the sanction of the Secretary of State has been given to the proposed changes.

WHITSUNTIDE CUSTOMS IN MANCHESTER.

MANCHESTER and the surrounding districts observe Whitsun-week as the great holiday of the year, and it is wholly given up to festivities of one kind or another. Thousands pour out of the city each day in every direction and to various distances on pleasure bent, and the railway companies reap an abundant harvest of third-class fares. With numbers of young men and women employed in offices, shops, and warehouses, it is an eagerly seized opportunity for spending a day or two with their friends at a distance. Moreover, it is the great festival of the various Sunday schools, and is looked forward to by the children as the brightest week of the year, and this year the weather has been exceptionally brilliant. Dressed in their best, and marshalled by their teachers, they assemble in Albert-square and then march in procession through some of the principal streets. On the Monday the children of the Church of England Schools, over 23,000 in number, so assembled, sang the Old Hundredth hymn, and then marched out of the square at 9.30 A.M. The rear was brought up by the boys of the Strangeways Refuge, who did not leave the square till nearly twelve. On Friday a similar scene was enacted by the Roman Catholic schools. These slow-moving, almost endless processions attract thousands of spectators, who line the streets through which the children pass. All traffic is stopped. The ends of the side streets are barricaded with lorries &c. Trams, cabs, carriages, and lorries come to a dead stop till the procession has passed. In however great a hurry, the most energetic man can but rarely cross the line of march, and those driving across the town to the various stations have to wait and let their trains go without them, unless they go round considerable distances by all sorts of circuitous routes. The organisation and management of these processions must be a work of much difficulty, but it would be well to carry it a little further. If occasional gaps were allowed—say between the different schools—the traffic would be less seriously interrupted. At one time it was too much the custom to take the children by rail to places sometimes as far as eighty or ninety miles away, starting early and returning late, with many of the younger ones half dead from fatigue and sometimes wet through. In such marvellous weather as that of last week no great harm perhaps would be done, but it may easily be imagined what half-drowned,

miserable little creatures a wet Whitsuntide would be accountable for. Many, very many deaths have in the past resulted from these Whitsuntide excursions. A more sensible custom seems now to prevail and long railway journeys are not so commonly taken. On the other days the various schools usually hire a field as conveniently situated as possible, in which the children play at various games. The whole of the country round Manchester—especially on the Lancashire side—observes Whitsuntide in the same fashion, so that it is easy to understand the anxiety very widely felt as to weather forecasts.

HABITS AND DISEASE.

THE tyranny of the body finds its most striking exemplification in the subjects of chronic disease, which without actually threatening life so restricts vitality as to modify the whole character of the individual. The old classification of temperaments may be largely interpreted in a pathological sense, for a real basis in organic derangement may be at the root of the physical and moral attributes that the individual possesses. This is, we fear, too often overlooked in persons who belong to the great class of hypochondriacs, for whom, it may be, less sympathy is shown than is deserved. The case of Coleridge is an illustration of this. A recent review of his life in the columns of the *Times* interpreted his "perpetual cry of ill-health" to mean "little less than opium and indolence." This opinion brought forth from the grand-daughter of Mr. Gilman "with whom the poet lived for more than eighteen years" a reply containing a most interesting account of Coleridge's chronic ailment penned by Mr. Gilman, which accounts for much of his idiosyncrasies of character and habits. The passages cited are as follow:—

"From some expressions in your letter I am induced to give you a short account of Mr. Coleridge's personal sufferings and their physical causes, which sufferings at the last were agonising to himself and to those about him. After his decease his body was inspected by two able anatomists appointed by Professor Green, a task too painful for either him or myself to perform. The left side of the chest was nearly occupied by the heart, which was immensely enlarged and the sides of which were so thin as not to be able to sustain its weight when raised. The right side of the chest was filled with a fluid enclosed in a membrane, having the appearance of a cyst, amounting in quantity to upwards of three quarts, so that the lungs on both sides were completely compressed. This will sufficiently account for his bodily sufferings, which were almost without intermission during the progress of the disease, and will explain to you the necessity of subduing these sufferings by narcotics and of driving on a most feeble circulation by stimulants, which his case had imperatively demanded. This disease, which is generally of slow progress, had its commencement in Coleridge nearly forty years before his death. To the general observer his disease masked itself; and his personal sufferings were hidden and concealed by his fortitude and resignation and by the extraordinary power he had of apparently overcoming and drowning them, as it were, at times in fervid colloquy."

The account here given of the post-mortem examination was probably not intended for professional perusal, and is therefore not so precise and definite as to be quite clearly interpreted. Thus it is somewhat puzzling to define the condition described in the right pleura. The large "cyst" mentioned could hardly have been a hydatid. It is more likely, we think, that it was really a pleural effusion, which seemed to be encysted from the presence of adhesions of the lung to the chest wall. If this be so then this effusion may be regarded as dropsical in character, occurring towards the close of life in a subject of chronic cardiac dilatation. The account which describes the enormous size of the heart and the extreme tenuity of its walls is silent as to the pericardium, but such a degree of enlargement may well have been due to universal adhesion of the heart to the pericardial sac, from inflammation of the latter in early life. The record, however,

suffices to prove that this intellectual giant must have suffered more than the world was aware of, and it can be understood that his "indolence" as well as his opium habit had a physical basis. It can only add to the marvel with which his achievements are justly regarded that one so physically disabled should have made such extensive and profound contributions to philosophy and literature. It is one more instance of the triumph of mind over body.

MEDICINE AND CRICKET.

WE congratulate Mr. W. G. Grace on the enthusiastic unanimity with which all classes of the community have welcomed the idea of presenting him with a testimonial. We entirely sympathise with a movement having for its object a material proof of the general recognition of the qualities which have raised Mr. Grace to his position of champion exponent of the national game and—by far the more wonderful thing to tell—have maintained him in that position for twenty years. Skill, endurance, patience, courage, strength, delicacy of movement, and alertness constitute in different proportions the endowments of the successful cricketer, and the pre-eminent champion at the game may therefore be credited with having displayed for years a just combination of them all. What better man can the sport-loving Briton find to honour than the author of such a display? Mr. Grace's connexion with our profession naturally turns our thoughts, subdued to what they work in, in one direction: Has his profession assisted in this maintenance of a remarkably high level of athletic prowess? And we make bold to say, Yes. We are not claiming that because the well-trained eye, the skilful hand, and the temperate mood equally comprise the chiefest virtues of the surgeon and the cricketer, a medical education should turn out experts at Lord's. Such a claim, by working both ways, would land us logically in the recommendation to our readers of Gunn for an enterostomy or the younger Druce for a litholapaxy! But we do claim that Mr. Grace's profession has counted for much in keeping him through two decades in the absolute front of the cricketing world. It has given him a wise insight into the rules of health, and furnished him with a knowledge of reasons that cannot have failed to be useful to him in times of physical or mental depression on the field, in unfortunate conjunctions of the game, even in seasons of comparative ill-success. And, considering that his display of ever-green vigour reflects honour upon the principles of medicine, we recommend to the favourable consideration of our readers the project of a national testimonial to our professional brother.

COLOUR MUSIC.

ON Thursday, June 6th, a large number of people interested in physics and in music were present, at the invitation of Mr. Wallace Rimington, an artist, to witness the first public demonstration of "a new art," the application to colour of qualities—rhythm, and the capability of instantaneous and varied combinations—which have till now been associated with music only. This Mr. Wallace Rimington effects by means of a "colour organ," the exact construction of which was not explained. The organ has a key-board like that of an ordinary organ, and by some ingenious contrivance the keys introduce corresponding coloured discs in front of a powerful arc or lime light, so that any particular colour, or combination of colours, may be projected on a screen. Each note on the key-board has its own colour, an octave representing the ordinary spectrum. The spectrum has been divided up into diatonic intervals or notes, the intervals being calculated according

to the rate of vibration at different parts of the spectrum in the same manner as with the musical scale. Single notes and chords can be struck on this organ with the same ease as on a pianoforte, and a rapid flitting of soft, transparent tints on the screen is the result. In order to show what could be done, extracts from Chopin were rendered simultaneously on the colour organ and on the pianoforte, and later selections from Wagner's "Rienzi" were given by an orchestra and the colour organ together. The effects were novel and in the main pleasing, but it was difficult to appreciate exactly the artistic value of the performance, the eye being at present entirely untrained for following and enjoying the rapid changes of colour. It was evident, too, that even if, which is by no means proved, the spectrum and musical octave are physically exactly analogous, there is a much less close resemblance in the psychical effects produced. Two points which were very obvious at the demonstration illustrate this point. Red and green occur close to one another in the spectrum, but the contrast in passing from red to green on the keyboard of the colour organ is much greater than that perceived with the analogues on the musical keyboard. Another difference was noticeable when a chord was struck. Instead of the chord being richer than its component notes, in many cases only a neutral greyish tint was obtained owing to the physiological antagonism of many of the colour sensations. Possibly more pleasing effects may be produced by compositions specially designed for the exhibition of colour in a rhythmical manner than by merely using pieces composed for musical instruments. The departure is a novel one, and we would congratulate Mr. Wallace Rimington on the perfection to which he has brought his mechanical contrivance and on being a pioneer of a new mode of artistic expression the ultimate developments of which may possibly rival painting and music.

DEFECTIVE NERVOUS SYSTEM IN A CAT.

In a recent number of *Brain* Dr. Risien Russell gives an account of the central nervous system of a cat, the symptoms in which during life had reminded Dr. Carruthers, from whom he received the animal, of the conditions presented by some dogs shown by Dr. Russell at a meeting of the Neurological Society in which ablation of one lateral lobe of the cerebellum had been practised. In this cat during life there was evidence of paresis of both posterior extremities and of the right anterior extremity, a condition corresponding to that met with in dogs after ablation of the right lateral lobe of the cerebellum. After death it was found that the skull presented no asymmetry, and the membranes were normal and not unduly adherent at any particular spot. The whole brain was below the average size, but there was no evidence of special atrophy or defective development of any part in particular except that the right hemisphere was a little smaller than the left. In the cerebellum notable changes were present. The whole organ was smaller than normal, smaller also in proportion to the small size of the cerebrum, but the right lobe was only about one-third of the size of the left. It was diminished in all its dimensions, and the right half of the pons and medulla shared in the defect, although not in such a marked degree. The two lateral halves of the cord did not seem to share in the asymmetry. The cranial nerves were smaller on the right side than on the left; the spinal ones presented no notable difference. Examination of the specimen after hardening and staining revealed further points of interest. The internal capsule and the crus cerebri on the right side were found to be distinctly smaller than those on the left. The right pyramid was completely absent except at the lowest part of the medulla, but at the level of the decussation a few fibres were seen occupying the region of the

anterior pyramid on the right side. At the decussation the normal left pyramid bifurcated, and while most of its fibres passed to the opposite crossed pyramidal tract a considerable number passed to the crossed pyramidal tract of the same side. Compensation by this means seemed to be so complete that with the exception of a possible slight difference in the lumbar region the spinal cord appeared to be quite symmetrical. Practically no trace of fillet fibres could be found on the right side, and on this side also the superior, middle, and even the inferior cerebellar peduncles were extremely diminutive. The cranial nerves also were found to be smaller on the right side, although they were not all equally so. The superior olivary body was slightly smaller on the right side, but the inferior on this side was very well developed, while on the left side it was very poorly developed. The nucleus of the funiculus gracilis and that also of the funiculus cuneatus were smaller on the left side than on the right. In conclusion, Dr. Russell points out that in this case there was clearly a well-marked condition of defective development on the right side of the cerebellum, pons, and medulla. The associated defects in structures of the left side and the integrity of certain structures on the same side, in which defect might have been expected to be present, are referred to in a series of deductions at the conclusion of the paper, to which we would refer the reader. The paper is also illustrated with a series of good collotype plates, and furnishes an excellent account of an interesting and instructive case, especially interesting in reference to the valuable experimental work recently carried out by Dr. Russell on the functions of the cerebellum.

THE "ALCESTIS" AT BRADFELD.

THE presentation of a Greek play to a modern audience, with, as far as may be, all the essential features of Greek tragedy reproduced, has been attempted many times, but never, we fancy, with such success as at Bradfield. This success mainly depends upon the play taking place in an open-air theatre constructed after the classical model, a fact which necessarily tends to make the representation far more realistic than any performance in a college hall. The dresses were faithfully copied from vases and sculptures, and the music was written strictly in ancient modes, the instruments being five lyres and four "flutes," or rather chalumeaux, a primitive form of clarinet. We must warmly congratulate Mr. Abdy-Williams, the composer, and his musicians for the way in which the music was rendered, and if a reed did "quack" now and then that is an accident which may happen to the most accomplished player. Of the play itself we can truthfully say that all the actors bore themselves with becoming dignity. One or two minor points in stage management may be noticed. The actor who played Death had his hands stained blue, while his face retained its natural colour. Now, if Death was meant to be made up like a person deeply cyanosed, which we presume was the case, his face ought to have been blue too. Again, when the *dead* Alcestis was brought on and her face uncovered by Admetus, she exhibited the rosy hue of perfect health. A little artificial pallor would have remedied this. Perhaps this may seem captious criticism, but when all else was so carefully done it seems only right to point out how the slight flaws which did occur could have been avoided. Mr. Wood Hill's reading of the part of Alcestis was very careful and all over-exaggeration successfully avoided, and Dr. Gray succeeded in making one feel really sorry for Admetus, a difficult task when we take into consideration what a miserable person he was. This is not the place to discuss the various theories which have been formulated as to Euripides' ideas of the legend; but for our own part we think a slight extension of Dr. Verrall's rationalistic theory will suit. Euripides was a sort of

Athenian Gilbert; the whole play is a solemn burlesque like "Engaged" or the scenes in "Iolanthe" between the two peers as to which of them shall sacrifice himself on account of Phyllis; while the obvious truism uttered at the last by the chorus, "The unexpected always happens," is in the purest spirit of burlesque. Be this as it may, the performance was most interesting, and the organisers are to be warmly congratulated, not only upon their dramatic success, but upon the excellent arrangements made for the comfort of their guests in the way of transport and seating accommodation. On June 11th the guests included many distinguished in literature and art. From Oxford came the heads of Trinity, Corpus, Brasenose, Oriel, and University, the Deans of Pembroke and Magdalen, from Cambridge Professor Sidgwick. Art was represented by Mr. Waterhouse, R.A., and Mr. David Murray, A.R.A.; education, from a Government point of view, by Lord Lingen, and by the Headmaster of Winchester as representing the public schools.

THE FUTURE OF CHARING-CROSS HOSPITAL.

IN our issue of last week we remarked that it was very doubtful whether the proposed transfer (as suggested by "X." in the *Times* of June 1st) of Charing-cross Hospital to South London would improve its financial position. "X." now writes to the *Times* saying that he has heard rumours that in consequence of his letter of the 1st inst. money has ceased to flow in, and subscriptions have stopped because the hospital is going to be moved. If this be the case when the removal is merely suggested, how much the more would it be when the change was accomplished? There may be "the potentiality of riches beyond the dreams of avarice" in Camberwell; but we still fancy that "Cælum, non animum, mutant qui trans mare currunt" would be the result of a move across the river. At a meeting of the council held at Charing-cross Hospital on Wednesday the schemes recently projected in *The Times* were repudiated, and the idea of entertaining any of the proposals on the lines suggested was emphatically rejected.

THE ELECTION TO THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT the election to the Council of the Royal College of Surgeons of England, which will take place at 1.30 P.M. on Thursday, July 4th, there will be five vacant seats to be filled. The three members of the Council who are retiring by rotation in accordance with the terms of the Charter of 1843 are Sir T. Spencer Wells, Bart., Mr. Jonathan Hutchinson, and Mr. Alfred Willett. Sir T. Spencer Wells, Bart., was elected in 1871 and re-elected in 1879 and 1887, and has therefore served on the Council for nearly a quarter of a century. Mr. Hutchinson was elected in 1879 and re-elected in 1887, and has therefore served for sixteen years. Neither Sir T. Spencer Wells, Bart., nor Mr. Hutchinson is a candidate for re-election. Mr. Alfred Willett, one of the present Vice-Presidents, who was elected in 1887 and has therefore completed one full term of office, is standing for re-election. By the lamented deaths of Mr. Hulke and Mr. Durham two other vacancies have been created. Mr. Hulke was elected in 1881 with the present President of the College, and re-elected in 1889, so that his term of office would have expired in 1897. Mr. Durham was elected in 1884 and re-elected in 1892, and his term of office would not have expired till 1900. The candidates who are returned to fill the vacancies created by the decease of Mr. Hulke and Mr. Durham will be elected as "substitute members" to complete the respective terms of office which Mr. Hulke and Mr. Durham would have enjoyed. The candidate who stands fourth on the poll will take the place of Mr. Durham,

whilst the seat of Mr. Hulke will fall to the fifth successful candidate. This system of "substitute membership" gives rise to much inconvenience and inequality and should be abolished. For the five vacant seats there are nine candidates, including Mr. Willett (Fellow, 1862; Member, 1859). In the order of seniority as Fellows the other candidates for election are: J. Ward Cousins (Fellow, 1860; Member, 1856), A. T. Norton (Fellow, 1867; Member, 1862), William Anderson (Fellow, 1869; Member, 1867), Alfred Cooper (Fellow, 1870; Member 1861), J. N. C. Davies-Colley (Fellow 1870; Member, 1868) H. T. Butlin (Fellow, 1871; Member, 1867), H. W. Page (Fellow, 1871; Member, 1869), and Frederick Treves (Fellow, 1878; Member, 1875).

PRESCRIBING DRUGGISTS.

AGAIN the old story. Frederick William Biggs of Cardiff had a son, Arthur, who was taken ill. The father, instead of sending for a medical man, applied to a druggist, who supplied him with some medicine. The child died from, as a post-mortem examination showed, acute bronchitis. The medicine had done no harm. The coroner thereupon censured the chemist for prescribing, in which censure the jury concurred, while they also very justly blamed the parents for not calling in a medical man sooner. This sort of cases will continue to occur until ignorant people can be divested of their fixed idea that a medical practitioner is a man who gives "bottles" each containing a specific remedy, or until druggists are prohibited from prescribing by law; and as anyone, no matter how ignorant, may prescribe, we fear that the latter course will hardly be followed.

AN ACTION BY A DENTIST FOR THE RECOVERY OF FEES.

AN action brought by a dentist for recovery of fees has recently taken place at Doncaster. The amount claimed was £33 12s. for professional services rendered to the family of the defendant, and of this sum £21 10s. were charged for the treatment of an "irregularity of the teeth." The defence set up was that the fees were excessive. Professional evidence was given on both sides, a verdict being returned for the plaintiff for the full amount, with costs. In fairness to the plaintiff it would have been difficult to have arrived at any other conclusion; while looked at from a general point of view the result is satisfactory, inasmuch as it shows that the law is willing to protect the professional man who charges reasonable fees against clients who place their own estimate on services they know but little or nothing about.

THE TRANSPORTATION OF THE DEAD IN AMERICA.

THE *Journal of the American Public Health Association* publishes a paper on the Innocuous Transportation of the Dead, by Dr. J. D. Griffith, in which he remarks: "Until we are educated to the point of the thorough sanitation of cremation the transportation of dead bodies by railways is, and always will be, a source of danger." This danger, however, we are happy to think, does not threaten our own country in the same degree as it does America, where dead bodies are quite commonly put in baggage cars along with, perhaps, twenty or thirty trunks. It is clear that if the person has died from an infectious disease and the coffin is not hermetically sealed, the luggage may become infected, and by its distribution could prove the cause of wide-spreading mischief. Not only this, but the health of the railway employes is menaced. In 1888 the National Association of General Baggage Agents, including most, if not all, of the main carriers of the United States, adopted a schedule of rules and forms to govern the transportation of corpses, in which it was suggested that a corpse should be wrapped in a sheet saturated with a strong solution of bichloride of mercury and packed in a specified casket.

The writer gives it as his opinion that many dangerous maladies have been spread by handling and shipping the dead body, and believes that the whole country must have benefited from these rules, as most of the State boards of health have not only approved but adopted them with little or no modification. It has been suggested that in all cases where a death occurs from an infectious disease the body should be interred in the same neighbourhood where the death takes place; but, as Dr. Griffith points out, endless trouble might follow with many people who would leave no stone unturned to enable them to remove the body if they so desired. This being so, the only practical suggestion seems to be that a portion of the baggage car should be provided with metal-lined compartments and be used exclusively for the purpose of conveying dead bodies from one place to another. By this means the risk of infection would be considerably minimised, both to the employes of railways and the travellers who entrust their trunks to the care of the railroad companies.

MR. GLADSTONE AND HIS CORRESPONDENTS.

No one, perhaps, except a statesman, can fully appreciate the meaning of Mr. Gladstone's request that no letters should be addressed to him during his absence from England. To the very young the postman is generally looked upon as a kind messenger who always brings glad tidings, and when adolescence is reached and the mischievous heathen deity has caused the pulse to quicken and the pupil to dilate the double knock is far from being an unwelcome sound. To the man of business, however, the postman is looked upon with far different feelings, and the sight of the Post-office messenger is very apt to call up in his mind a vision of a large batch of letters marked urgent and confidential, which for the most part when opened will be found to contain advertisements relating to somebody's New Neuritic Nervine, or a request for a subscription to the Mutual Protection Society of Nostrum Advertisers. Such things are not calculated to conduce to a peaceful state of mind even in the ordinary man of business, and are certainly not likely to soothe an over-worked statesman. It is said that Lord Rosebery during his recent illness was the recipient of a considerable number of letters marked private and confidential which contained recipes for insomnia, and we do not doubt that the late Premier has received similar well-meaning attentions during the time he has served the State. Mr. Gladstone, who is now in his eighty-sixth year, was found, when examined by his medical attendant in the early part of 1894, just before his resignation from active political life, to have a vigorous heart, a good appetite, sound lungs, and muscular limbs, and to be full of vivacity and vitality after sixty years of Parliamentary life. He left England for his annual rest on Tuesday last—if such a man can be said to ever take rest,—when his temperature was 98° F., and he started in excellent spirits after a very good night's rest. We sincerely hope that he may return in good health, and that his simple request that he may not be worried by a needless correspondence may be complied with.

THE CORONER OF BIRMINGHAM AND THE COUNTY CONSTABULARY.

We commented last week on the action of the county constabulary in resisting the request of Mr. Oliver Pemberton, the city coroner of Birmingham, that a man named Saunders, under arrest upon the charge of murder, should be present, if he so desired, at the inquest upon his victim. The bare fairness of the proceeding would seem to everyone to justify Mr. Pemberton in his objection to subordinate resistance, and we are glad to say that after a week's delay, and

at the cost of trouble to himself and the jury, he secured the presence of the man. The Commissioners of Prisons sent an order to the Governor of Warwick Gaol directing that the prisoner should be brought to the coroner's court independently of the action of the constabulary. The verdict that was eventually returned showed how completely the coroner was right in his action, and we hope that other coroners finding themselves in the same position will use this example as a means to their end. The case, it may be noted, was not without interest to the profession from a purely medical aspect. The evidence went to show that the victim had been stabbed about the head with a clasp-knife, but as the external injuries—two stabs, one above the left eye and the other below the left ear—appeared to be slight, and were accompanied by no signs of serious mischief, no objection was raised at the hospital to his desire to return home. This was on the Saturday evening, May 25th, but on the Monday morning symptoms of cerebral inflammation were present, and he was detained at the hospital. He was trephined, but died on Tuesday of meningitis. The post-mortem examination showed that the knife had penetrated the brain substance for some distance, though the injury to the skull was one which it would have been impossible to detect.

THE INFORMAL PURCHASE OF POISONS.

We print under this heading in another column a letter from a Brighton surgeon who, in reference to the numerous cases of dog-poisoning that have recently occurred in Sussex, points out the extreme ease with which it is possible for laymen, complying with no formality whatever, to procure large quantities of deadly poison from wholesale druggists. The anecdote which he relates in his letter (p. 1543) discloses a distinctly illegal proceeding, and one which we hope is not common, which, indeed, cannot long be common without the occurrence of some terrible accident. The business of wholesale dealers in supplying scheduled poisons, as the *Pharmaceutical Journal* points out this week, is only exempted under the Pharmacy Act, 1868, in so far as they supply them "in the ordinary course of wholesale dealing." Transactions with private individuals who require poisons for their own use are not covered by this exemption, and it is quite possible, therefore, that if satisfactory evidence of such illegal sales were forthcoming, the Pharmaceutical Society would be able to move in the matter and check a practice which is both unworthy of any respectable wholesale house and pernicious in its tendencies.

THE MANUFACTURE OF COMPRESSED GASES.

In a leading article in *THE LANCET* of March 23rd we expressed the hope that the Government would see its way to institute with little delay an inquiry with the view of placing the manufacture of compressed gases under some kind of legislative control. Our remarks were based upon the explosion of a gas cylinder at Fenchurch-street Station a short while ago, by which one man lost his life, while the damage done to property was by no means trifling. We now learn with satisfaction that the Departmental Committee which has been appointed by the Home Secretary to inquire into and report on the manufacture, filling, and use of gas cylinders will meet shortly to elect a chairman and arrange certain preliminaries. Visits are then to be paid to the centres in London and in the country where these cylinders are produced, and expert evidence is afterwards to be taken on the whole question of the manufacture of compressed gases. It will be remembered that the cause of the cylinder exploding at Fenchurch-street Station could not easily be accounted for, and the evidence given at the inquest was somewhat conflicting. The explosion may have been due to the

cylinder receiving a shock by coming suddenly into contact with a hard surface like the stone platform, in which case the metal must have become brittle or crystalline through neglect to re-anneal it, or to the cylinder containing inadvertently a mixture of hydrogen and oxygen, besides some oil which may perchance have trickled down from the connecting screws of the cylinder into the interior, and, heat being established by the oxidation and possible ignition of the oil, the union of hydrogen with oxygen with explosive violence was inevitable. Whatever may have been the cause it is perfectly clear that the subject is ripe for inquiry, especially as this comparatively new industry (the compressing of gases such as hydrogen, oxygen, carbonic acid, &c.) is largely on the increase. We are glad, therefore, to learn that the Home Office has so far acted with the promptitude which the question demands; the committee is to sit on the 24th inst., and the proceedings will not, it is thought, occupy longer than a fortnight. We await their report with interest.

"LE MÉDECIN MALGRÉ LUI."

AN account appeared recently in the columns of the *St. James's Gazette* and the *Pall Mall Gazette* of an ingenious application of the "put-a-penny-in-the-slot" system. The machine is figured in the likeness of a man, and reduces specialism to a fine art, for instead of the one or two slots which the carnal and earthly sweetmeat or cigarette machine has, this is provided with slots corresponding to every member of the body. Has anyone a headache? On inserting a coin into the slot in the head the machine, after due consideration, hands out a prescription for the evil in question. The machines do not make up medicine, but the address of the nearest druggist is given. It only remains for some enterprising philanthropist to supply London with these machines, and the relief to the overcrowded out-patient department of our hospitals would be marked. Gone, too, would be the occupation of "Lennox" and "Bernal, M.D.," of the gentleman who appeals so eloquently from the boardings with "Why suffer longer?" and all the other newspaper prescribers.

THE CARMARTHEN DROWNING CASE.

IN our issue of June 8th we noticed the severe strictures passed on Mr. Bowen-Jones by the coroner. We have since had the opportunity of perusing a report of the inquest contained in a local paper, with the result that we adhere fully to our previous remarks. It appears that a boy on his own initiative—prompted, no doubt, by a most excellent motive, instinctive humanity—went to Mr. Bowen-Jones and said that aid was wanted as some children had fallen into the water. The lad deposed that he was so excited at the mishap and with running that he was not certain what impression his words would exactly convey to Mr. Bowen-Jones, but that he gave that gentleman to understand medical aid was needed. It is alleged that Mr. Bowen-Jones asked the boy who was going to pay his fees if he went. From information supplied by Mr. Bowen-Jones it seems that unfounded rumours of accidents are not uncommonly raised and circulated, and that on several occasions he has attended calls only to find that he was not wanted. As regards the inquiry as to the payment for his attendance we are assured that it was only made in a playful way, and indeed this seems to be the most reasonable explanation of Mr. Bowen-Jones's words, for he would not expect to receive a guarantee of remuneration from a lad under the circumstances narrated. We learn that Mr. Bowen-Jones at the time was on his way to minister gratuitously to a patient, and therefore it was not greed of gain that deterred him from acting on the statement made by the

boy. But apart from these facts, which we consider Mr. Bowen-Jones has reasonably explained, we maintain that the coroner would have more fully acted in the spirit of judicial impartiality if he had adjourned the inquest for the purpose of taking Mr. Bowen-Jones's evidence. To condemn him unheard, and that, too, in the strongest denunciatory terms, runs counter to our sense of equity. No doubt the coroner was entirely within his legal rights in taking the course he did, but there are statements which are privileged, and which yet do not meet with the sanction of abstract right. At the inquest the jury were not unanimous in adding a rider censuring Mr. Bowen-Jones for his conduct, a fact showing that there were some at least who felt that such proposed rider was not justified by the evidence before them. It is matter for regret that the coroner did not identify himself with the course these gentlemen adopted.

THE SPREAD OF INFECTION.

A CASE recently decided in the Borough Court, Brighton, is instructive in its bearing upon the isolation of cases of infectious disease. The defendant was summoned for having travelled from Brighton to London by rail and cab while conscious that he was suffering from scarlet fever. In defence he pleaded ignorance of his condition, and alleged in support of his statements the uncertain opinion of his medical attendant respecting the early phase of his disorder. This plea not being proved, a sentence of £5 and costs was inflicted. This unfortunate sequel to a successful recovery possesses more than one feature of medical interest. It impresses the great importance of dealing cautiously even with cases of doubtfully infectious character, and of treating them so as to cover the possibility of contagion. As regards their removal, this of course is undesirable as much in the interest of the patient as of the public. Where it is for any reason imperatively called for, the needful arrangements ought to be entrusted to the local sanitary authorities.

A HEALTH CRUSADE.

A PROPOSAL by Mr. Samuel Osborn, F.R.C.S., which was discussed at the Slough Ruridecanal Conference, touches a subject the importance of which is only equalled by the extent of its application—that of hygiene among the poor. A motion "that combined action be taken by the clerical and medical professions for the purpose of inculcating among the poor some of the more important principles of hygiene," notwithstanding a certain apparent confusion of ideas, cannot but evoke the respect due to its disinterested sincerity. We do not quite see how the clergy can be joined in partnership with the medical profession as teachers of hygiene. Mr. Osborn explains himself, however, and the riddle no longer seems to be inscrutable. He does not desire to form within the ranks of the Church a new staff of medical officers of health, but rather to obtain for the existing members of this order, and for such of their purposes as may be classed as a species of first aid in sanitation, the local influence wielded by the spiritual arm. Fresh air, cleanliness and thrift, simple, nutritious, and cheap feeding, good plain cookery, and regulations as to burial,—such, in brief, are the subjects which it is proposed to bring within the active sphere of the new administration. The same object has been in some degree attained already in North Bucks by the appointment of what are called "health missionaries," a class of women who visit among the poor and teach them the outlines of sanitary science as applied in the practice of household duty. Those of us who know something of the gross ignorance and indolence which prevails in many country districts respecting this important subject will welcome help which is reliable from whatever quarter. We hope, too, that sanitary authorities, being thus befriended with assistance, will exert

themselves, in country as in town, to incorporate the facts of sanitation more and more with the daily life of their respective districts.

DIPHTHERIA IN LONDON.

THERE are at present no signs of diminution of diphtheria prevalence in London such as were apparent some time back, seeing that, whether regard be had to the cases or to the deaths, the disease has been maintaining itself in recent weeks in a manner which suggests endemicity of considerable proportions. In the four weeks ended May 18th there were 638 notified cases of the disease in London, and 135 registered deaths therefrom, the per case mortality thus yielded being just under 21·2 per cent. In the three weeks that have since elapsed the cases have averaged 165, or nearly 500 in all, and the deaths 111, the per case mortality in the successive weeks having been 22·3, 25·2, and 20·0 per cent. In the four-weekly period just named the disease was present in all the London sanitary areas save two; and of the 638 cases there were 20 and upwards in each of the 15 districts, the largest numbers occurring in Camberwell (63 cases), Poplar (46 cases), Lambeth (34 cases), and Hackney (33 cases). In the four weeks ended last Saturday the registered deaths from diphtheria numbered respectively 41, 37, 41, and last week 33, a figure 7 in excess of the corrected average of the corresponding week of the preceding decennium. Of these deaths 3 each are credited to Paddington, Islington, Hackney, Shoreditch, and St. George-in-the-East sanitary areas. All the 33 were in persons aged under twenty years, and 23 at ages one to five years. The admissions to hospital were 86, as compared with 87, 79, and 88 in the three preceding weeks, at the close of which the patients remaining under treatment numbered 484, 492, and 508, as compared with the increased total of 529 last Saturday. In Greater London last week there were 16 registered deaths from the disease, of which no fewer than 8 were in the West Ham district.

INSECTS AND CONTAGION.

IT is generally understood that the stings of some insects are essentially poisonous in a greater or less degree, and must therefore be early and carefully treated. Pain alone in such cases will suffice for a danger signal, and few when thus warned would care to neglect the puncture made by a hornet, a wasp, or even a bee. The fact that other insects, like some species of fly, are capable of equal or even greater mischief, is not so commonly known as it ought to be. The recent death of a woman Kingston from septic erysipelas thus caused may be quoted in illustration. In accounting for such occurrences two points are specially noteworthy—namely, the condition of health of the person attacked, and the previous *habitat* of the assailant. In no case probably is it possible to define exactly the influence exercised by each of these contributing factors. This much we know, however, that no matter how trivial or how great the effect of the conveyed poison, it is much enhanced by all conditions of weakness or blood impurity existing in the sufferer. A mere midge or gnat-bite in one person will prove almost as serious in its effect as a septic wound in another. There are in the system all the materials for a conflagration, and a spark may light it up as well as a fire-brand. The habits of insects afford a clue to the seeming vagary of their occasional and accidental virulence. The sting or the mandibles, which perhaps were buried an hour previously in some putrid sore, excreta, or offal, cannot penetrate a living tissue without leaving in it something of the same putrid character. It is safer therefore for the medical practitioner to regard each and every injury of this kind, however slight, as a possible source of illness, and at once to contrive its relief

by poulticing, antiseptic compresses, or like means. For prevention we can suggest no better safeguard than some form of antiseptic veil, to be worn after the manner suggested in THE LANCET of Aug. 6th, 1892.

SIR WILLIAM MACCORMAC has received an official letter, signed by the president and secretaries of the Belgian Surgical Society, saying: "Nous avons l'honneur de vous informer que la Société Belge de Chirurgie, dans sa séance du 27 avril dernier, vous a conféré le titre de Membre Honoraire en témoignage des grands services que vous avez rendus à la science chirurgicale." We congratulate Sir William MacCormac on this intelligent and graceful appreciation of his surgical work.

ON Friday next, June 21st, at 6 P.M., in the Town Hall, Kensington, an interesting ceremony will be performed. The Marquis of Lorne will preside at the presentation to Mr. and Mrs. J. J. Merriman of a testimonial subscribed by their friends in Kensington in recognition of Mr. Merriman's services as a medical man. The Merriman family have been medical men in Kensington for over 100 years.

THE Cavendish Lecture of the West London Medical-Chirurgical Society will be delivered at 8.30 P.M. on Thursday, June 20th, in the Vestry-hall, The Broadway, Hammersmith, W., by Sir J. Crichton-Browne, M.D., F.R.S., who has taken as his subject "Dreamy Mental States." A conversazione will be held after the lecture.

THE annual dinner of the Army Medical Staff will be held in the Whitehall Rooms of the Hôtel Métropole at 7.30 P.M. on Monday next, the 17th inst. Those intending to be present are requested to communicate immediately with Brigade-Surgeon-Lieutenant-Colonel Hector, 25, Anerley-park, Anerley, S.E.

THE Bowman Lecture of the Ophthalmological Society was delivered to-day (Friday) by Dr. Gowers, who took as his subject "Subjective Visual Sensations." We shall print Dr. Gowers's able paper in an early issue.

THE annual meeting of the British Dental Association will be held in Edinburgh on Aug. 28th, 29th, 30th, and 31st.

THE death is announced, at an advanced age, of M. Verneull, the eminent French surgeon.

THE ROYAL SOCIETY CONVERSAZIONE.

"LADIES' night" at the Royal Society, which this year was held on Wednesday last, sees a repetition of the things shown at the previous *soirée* held in May,¹ which to science is as the opening of the Academy is to art—a revelation of the year's work and of the year's developments. Probably the council arrange that the exhibits that are found to attract the greatest interest at the first conversazione shall be shown again for the delectation of the fair visitors and friends of the Fellows. Thus for brilliant effect the projections upon the screen by means of a lens and mirror of the molten contents of the electrical furnace of Professor Roberts Austen, which is used for the preparation of the diamond form of carbon and for the melting of chromium and similar refractory metals, could hardly be rivalled, while the four globes exhibited by Mr. W. N. Shaw, in which were illustrated the phenomena associated with the formation of cloud, were equally attractive and pretty, though they were not concerned in the employment of such powerful forces. Again the interesting collection of Mr. W. T. Burgess, consisting of cultivations of alices of potatoes over which flies

¹ THE LANCET, May 4th, 1896.

infested with a chromogenic organism had walked, demonstrating in a most striking way the extreme possibility of the transmission of infection by flies, was, as the importance of the exhibit demanded, shown once more. The spectra of argon and of helium (or helion, as we should now write it) mixed with argon were of course re-exhibited by Professor Ramsay, and the interest in these recent discoveries was accentuated by the excellent series of photographs shown by Professor J. Norman Lockyer. Amongst them were the photographs of the apparatus employed for collecting the gases obtained from minerals by the distillation method *in vacuo*; the photographs of the spectra of Bellatrix and of a part of the solar chromosphere, showing coincidences with the lines photographed in the spectra of gases from "uraninite"; and photographs also of the spectra of the new gases. The ingenious electrograph of Messrs. Nalder Brothers and Co. attracted a good deal of attention. In this process the fabric is first damped and then a current is passed for about two seconds from a silver die, the metal of which in contact with the fabric appears to form a cellulose compound, which is colourless. On reversing the current, however, the silver in the fabric is reduced, the result being that an indelible mark of metallic silver in the tissue is made, which to some extent corresponds with that produced by marking ink. Mr. Francis Galton showed the value of observing minutiae in finger prints. In a very distinct photograph in a case of twins, whose portraits, classificatory measures, and finger-print *formule* were closely alike, it could be clearly seen that the finger-print *minutiae* are quite different. Excellent demonstrations are commonly expected of Mr. Boys, who in past years has been known for his remarkable experiments with bubbles and the velocity of bullets. On the present occasion he showed on the screen the exceedingly pretty effect of the ripples produced by tuning forks upon the surface of mercury, which are so small and travel so quickly as to be invisible unless illuminated either instantaneously or intermittently at the proper rate. Dr. J. Joly exhibited his photographs in natural colours, the process of taking and reproducing them differing in no way from ordinary photography upon the dry plate, except that the sensitive plate is exposed behind a screen in the camera in particular colours. The colours so registered are brought to view by means of a superimposed screen lined with three other colours. One of the points of interest connected with the exhibit of the Marine Biological Association consisted in the fact of the efficacy of formic aldehyde in dilute solutions in preserving transparent organisms.

Lastly, the interest shown in the exhibit of the Postmaster-General in the archives room was almost beyond the limits of accommodation afforded by the room. Here for the first time telephonic communication was established with Edinburgh, Glasgow, Belfast, and Dublin. Those who were fortunate enough to secure receivers were amused and almost awed to hear the spoken communications of individuals in Dublin, which by the route taken by the cable was 467 miles away. At Edinburgh and Glasgow a musical programme was provided, the performance of which could be heard with marked distinctness, the notes of the bagpipe from the latter place being particularly audible. The wires to Ireland extend through Leeds and Carlisle to Portpatrick, thence by cable across St. Patrick's Channel to Donaghadee, thence to Belfast and Dublin. The charges for communication between the principal towns varies from 6d. in the case of Glasgow to Edinburgh, to 7s. 6d. London to Dublin, for three minutes' conversation. The line is built with the heaviest copper wire ever erected, and weighs on an average 800 lb. per mile.

REPORT OF THE COMMITTEE ON PRISONS.

IV.¹

Is the present prison system sufficiently deterrent? We have already pointed out that it is the opinion of the committee that so far as first offences are concerned the present prison treatment in convict and local prisons is amply sufficient for the purposes of deterrence. The Royal Commission of 1883 expressed an opinion that the penal servitude system

then in force "appeared not to be sufficiently dreaded either by those who have undergone it or by the criminal classes generally." The Royal Commission of 1879, however, declared, after full investigation, that "the system [i.e., in the case of convicts] is effective as a punishment"; and the committee go on to say that "a similar opinion in relation to local as well as convict prisons has been expressed by the most competent witnesses whom we have examined." But here a question of the utmost importance arises, that of the length of sentences. Among the numerous witnesses examined there appeared to be a consensus of opinion on two points in this connexion. First, they agreed that as a general principle short sentences were most desirable in the case of first offenders and where extenuating circumstances could be shown to exist. Secondly, they agreed that short, non-cumulative sentences on old criminals and on persons habitually drunk and disorderly were almost altogether ineffectual. Although this leaves out of consideration that group of offenders who are brought to trial for the first time because they have committed serious crimes against property or gross or violent crimes against the person, we may fairly take it that this consensus of opinion has reference to the great bulk of persons engaging in crime and coming under penal discipline in prison. This being so, we arrive at an excellent basis whereon to build up a scheme of practical dealing with the vast majority of offenders, so long as due care is taken not to let the term "first offenders" become too elastic in its application. It may not be out of place here to point out that the factors of which punitive deterrence in prisons is made up are mainly five in number—viz.: (1) deprivation of liberty, (2) restricted diet, (3) compulsory labour, (4) disciplinary training in regular and cleanly habits, and (5) interdiction of social companionships and comforts. But it must not be forgotten that, although these factors are primarily punitive and repressive, they are all more or less the elements upon which consistency and strength of moral character are based, and that it is impossible to do without them in any efforts that are made in moulding or reforming the moral tone of individuals. We believe the committee themselves would recognise this position. Speaking of what they refer to as the "character of necessary changes" they say: "We think that the [prison] system should be made more elastic, more capable of being adapted to the special cases of individual prisoners; that prison discipline and treatment should be more effectually designed to maintain, stimulate, or awaken the higher susceptibilities of prisoners, to develop their moral instincts, to train them in orderly and industrial habits, and, whenever possible, to turn them out of prison better men and women, both physically and morally, than when they came in." This is the veritable Utopia which all prison legislators and philanthropists are ever dreaming of and looking forward to. It is an ideal which is far more easily planned out than put into practice. The "less elastic" system has proved to be fruitful of good results, so far at least as it can lay claim to having been a means to an end, that end being the reduction of the prison population; and if a more elastic policy is now to find favour we feel sure that the elasticity must be instituted as an adjunct to, and not as a substitute for, those factors of deterrence to which we have referred, and which form the groundwork of the existing prison system. This, we think, ought to be made sufficiently clear before any fancied "new broom" methods are placed upon their trial. The committee are satisfied that they have not been able to solve the knotty problem of "crime" in its various relationships, and they speculate on the subject in the following terms. "Crime, its causes and treatment, has been the subject of much profound and scientific inquiry. Many of the problems it presents are practically at the present time insoluble. It may be true that some criminals are irreclaimable, just as some diseases are incurable, and in such cases it is not unreasonable to acquiesce in the theory that criminality is a disease and the result of physical imperfection; but criminal anthropology as a science is in an embryo stage, and while scientific, and more particularly medical, observation and experience are of the most essential value in guiding opinion on the whole subject, it would be a loss of time to search for a perfect system in learned but conflicting theories when so much can be done by the recognition of the plain fact that the great majority of prisoners are ordinary men and women, amenable, more or less, to all those influences which affect persons outside." We have italicised the last clause because to our mind it contains for all practical

¹ Parts I., II., and III. were published in THE LANCET of May 4th, 18th, and 25th respectively.

purposes the pith of the whole matter. We are not unwilling to accept the compliment honestly paid to the work done by the medical profession in this relation; but we are strongly of opinion that, as the committee imply, it is only in the small minority of imprisoned criminals that the pathological and psychological phenomena are at all likely to take us outside the pale of common sense or beyond the ordinary rules which guide conduct in our everyday life.

The committee ask the question: "Upon what does the reformatory influence which we desire to bring to bear more fully on the prison system depend?" And they answer: (1) the administrative authority; (2) individual effort; and (3) a proper classification of prisoners. We have already dealt with the principles upon which the committee are anxious that the classification of prisoners should be worked out. They are, perhaps, not much more than a development upon existing lines, but we believe them to be sound and not impracticable. On the subject of (1) administrative authority they say: "The population of every prison is a community in itself, changing with greater or less rapidity, but composed of individuals of varying character, aptitude, and history. For purposes of prison discipline it is comparatively easy to mass them all together, to call each of them by a number, and by a cast-iron system to make them all go through the same tasks, observe the same hours, and lead the same lives. But under this orderly equality there exist the most striking inequalities. The hardened criminal bears the discipline without much trouble; others are brutalised by it; others suffer acutely and perhaps are permanently weakened by it in mind and body. It is impossible to administer to each man a relatively exact amount of punishment. But yet it is these very inequalities which often must produce that bitterness and recklessness which lead on to habitual crime. These inequalities must exist under the best available system. But the responsible authorities of the prison should have sufficient time at their command to observe prisoners individually, and sufficient discretionary power to give or obtain for an individual prisoner that guidance, advice, or help which at such a crisis in his life may make a priceless change in his intentions or disposition, and it should be the duty of the central executive to coöperate with the local officials in carrying out satisfactorily this most important part of their functions." They go on to say as to (2) that without an excessive and impossible increase in the number of higher prison officials adequate individual attention to prisoners "could not be given. But the warders could be trained to do some of this work, and under proper rules and regulations outside helpers could be brought in to supplement the work of the prison staff. Ordinary amateurs, as a rule, would be worse than useless. There are, however, many men and women in every centre of population who by training and temperament are amply competent to render valuable assistance." We have no doubt that if the higher prison officials had time to devote to the work they would be able to exercise a beneficial personal influence upon the characters of a sufficient number of prisoners to justify larger efforts in this direction being made, but that such influence could be made to permeate any large proportion of the inmates of a prison is very doubtful. We are far from sanguine about the good results that the committee would lead us to expect from the operative interference of warders, even if they could be "trained," in "awakening the higher susceptibilities of prisoners and developing their moral instincts." The most that could be expected in this direction would be in the selection of warders of an honest, manly, and not unsympathetic cast of mind—men whose manner and example would tacitly impress themselves upon the prisoners with whom they are brought in contact, and whose conversation (when available) would be wholesome and sensible.

The "mark system," which has done so much in convict prisons to stimulate industry and good conduct, is said to "work well." The committee were given to understand that it is the practice to restore marks forfeited by inadvertence or some trivial offence subsequently compensated for by diligence and good conduct, and they commend the practice. They are also of opinion that prisoners should not forfeit marks by reason of physical or mental weakness or illness. "We considered," they say, "whether the power to earn remission of sentence should be extended from convict to local prisons. It is difficult to see the logic or the advantage of allowing a three-year convict to earn a remission of one-fourth of his sentence, and of forbidding a local prisoner sentenced for eighteen months or

two years to earn any remission. We suggest that the remission system might be extended to local prisoners sentenced to the longer periods." Some difficulty—not a very great one, it is true—might arise in altering the apportioned length of sentences which, but for the length, are to be regarded as in all respects identical. But apart from this, when the length of sentence comes to be reckoned in years, and not months, there can be no doubt that the longer the sentence the greater is the intensity of that weariness of heart which the "long vista of years" may produce, and which almost demands the introduction of some bright element of hope such as that of which the mark system is the embodiment.

PORTSMOUTH MEDICAL UNION.

We append the prospectus of this new association, whose objects are thereby sufficiently defined, and we wish it all good fortune in safeguarding the interests of the profession, promoting good fellowship and an intimate *entente cordiale* between the medical men of the neighbourhood, and in securing for them the strength that is given by union.

The positive necessity for some organised action by practitioners for protection against unfairness and encroachment has become very urgent. No one who has read the recent correspondence in our columns on this subject, or who is conversant with the whole story of the battle of the clubs at Cork, can doubt that the profession often nowadays finds itself placed where opposition to grave abuses, so far from being evidence of cantankerousness or greed, is the only course that is left to the self-respecting man who sets a proper value upon his services.

GENERAL OBJECTS.

1. To safeguard and support the interests of the medical profession in the town and district.
2. To encourage cordial relations and amicable feelings between medical men practising in the district.
3. To enable members to obtain the advice and united support of the local profession.
4. To give opportunities of discussion and interchange of views on the business side of medical practice.
5. To obtain the combined action and consolidated influence of members of the union upon points of difficulty which may arise from time to time in local practice.

PARTICULAR OBJECTS.

1. To consider and take action upon the relations of medical officers with friendly societies and medical aid associations, and with regard to Poor-law and other official appointments.
2. To establish, maintain, and circulate among members of the union a patients' black list.
3. To promote the improvement of medical fees.

OBJECTS WITH REGARD TO FRIENDLY SOCIETIES.

1. To obtain the united action of members to enforce a wage limit.
2. To enforce payment for certificates by members of the club who do not subscribe to the surgeon's fund, and for all certificates not belonging to the club.
3. To enforce requirement of medical examination of new members and an examining fee.
4. To raise the rate of subscriptions for juveniles.
5. To alter the tenure of office to a suggested three months' notice on either side.
6. To refuse the admission to medical benefits of visiting members except after satisfactory medical examination.
7. To obtain the united action of members of the union with regard to the admission of females to the medical benefits of friendly societies.

PROPOSED RULES.

1. The society shall be called the Portsmouth Medical Union, having for its chief object to safeguard and support the interests of the medical practitioners in the town and district.
2. Every registered medical practitioner shall be eligible for membership.
3. Each member shall pay an annual subscription of 5s., due on June 1st in each year.
4. The affairs of the union shall be governed by a president, two vice-presidents, hon. secretary and treasurer, and a committee of six members, the above officers being *ex-officio* members of the committee. At committee meetings four shall form a quorum.
5. All officers, including the committee, shall be elected at the annual meeting to be held in the month of June in each year.
6. The committee shall have power to fill up vacancies in their own body.
7. The committee shall meet once a month, or when convened by the hon. secretary, to consider applications for advice or assistance, but may call a general meeting at any time if considered necessary.
8. A special general meeting shall be called by the president at any time upon a requisition signed by six members, such special meeting to consider no other topic than that for which the meeting was called.
9. Every member of the union shall give a personal pledge not to oppose any practitioner in any course of action which he may take in his official capacity concerning any public appointment with the concurrence of the committee.
10. Any member acting, in the opinion of a special meeting called for

the purpose, contrary to the laws and regulations of the union shall, upon a majority of at least three-fourths of the members present, be suspended or expelled (and without appeal) from the advantages of the union.

11. A special meeting called for the purpose of considering the conduct of any member of the union shall only be convened after fourteen days' written notice has been sent to the last known address of each member, and such notice shall state clearly the purpose for which such meeting is convened.

12. No new law shall be adopted, and no existing law be altered or rescinded, except at the annual general meeting, or at a special meeting called for the purpose, and fourteen days' notice of such proposed alterations, signed by at least three members, shall be sent to every member of the union in the circular convening the meeting.

The officers of the Portsmouth Medical Union are as follows:—President: Mr. F. Lord, Vice-Presidents: Mr. James Green and Dr. Lyander Maybury. Committee: Mr. Goss, Mr. Kythin, Mr. Hackman, Mr. Colt, Mr. Emmett, and Mr. McGregor. Hon. Secs. and Treasurer: Dr. Frederick Pearse, Dr. J. Blackman (and Treasurer). The temporary address is 5, Pembroke-road, Portsmouth.

CAMBRIDGE SUMMER SCHOOL OF MEDICINE.

A SHORT time ago we published a provisional notice of the Cambridge Summer School of Medicine. We have now received a detailed programme of the proceedings as far as they are at present arranged. The subjects for laboratory demonstration have not yet been settled, nor have those for the hospital clinics, but special notices will be issued later, together with more definite information.

The session will commence on Monday, July 1st, and will open with a conversazione in the Physiological Laboratory and with an address by Sir George Humphry. At 10.15 on Tuesday, Wednesday, and Thursday mornings clinical lectures will be delivered in Addenbrooke's Hospital by members of the staff; on Friday a pharmacological demonstration will be given in the Physiological Laboratory. At 10.30 all through the week physiological, alternating with pathological, demonstrations will be given. The rest of the time will be occupied with various lectures and addresses, garden parties, visits to colleges, organ recitals, &c.

It is to be hoped that the profession will take advantage of the offer so generously made by the Cambridge Medical School, an offer which shows University Extension in its best aspect, for apart from the professional knowledge to be gained there can be no more delightful place in which to spend a week of summer weather than Cambridge, unless, indeed, it be Oxford. We hope the day is not far distant when Oxford will offer the same combination of intellectual and physical pleasures that her sister University is offering to those who have never tasted the pleasures of university life.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

A GENERAL MEETING of this association was held at 11, Chandos-street, Cavendish-square, on Thursday, May 16th, under the presidency of Mr. Conolly Norman, F.R.C.P. Ire.

The President proposed the following resolution: "That this association assembled in general meeting desire to express their deep sense of the loss which the association has sustained in the death of Dr. Daniel Hack Tuke." This was seconded by Dr. Blandford, supported by Dr. Rayner, and carried unanimously, and the honorary general secretary was requested to send a copy of it to Mrs. Tuke.

Dr. Mercier then read a paper on Collective Investigation. He referred to the Collective Investigation Committee of the British Medical Association, and said that although the results of its labours did not equal the sanguine anticipations of its promoters, yet they were by no means fruitless or unimportant. This association had advantages and opportunities for collective investigation that were vastly superior to those of the British Medical Association, for their members had their patients under constant observation, and had the regulation of the whole life of their patients. Dr. Mercier then took as an example the subject of epilepsy, giving a number of instances of questions that were awaiting solution, and claimed that they could be solved by the method of collective investigation, and by that method only. He concluded by moving that a committee should be appointed to

deal with the matter and that members should be invited to coöperate.

Dr. Andriezen had arranged to read a paper on *Insomnia and Cephalalgia and their Correlated Brain Changes in Early Alcoholic Insanity*, but at the last moment a telegram arrived saying that he was too unwell to be present. After the meeting the members dined together at the Café Royal.

THE EXTENSION OF THE WEST LONDON HOSPITAL.

THE Duke of Devonshire presided on Wednesday afternoon last at a meeting at Devonshire House in aid of the proposed building fund of £20,000 for the extension of the West London Hospital. Among those present were H.R.H. the Princess Louise, the Marquis of Lorne, Cardinal Vaughan, Sir A. Borthwick, M.P., Mr. Hayes Fisher, M.P., Sir William Priestley, M.D., Mr. Leopold de Rothschild, and the Rev. the Hon. E. Carr Glyn, the rector of Kensington.

His GRACE, in opening the proceedings, expressed his regret at the unavoidable absence of Mr. Arthur Balfour, whose powers of eloquence, however, he thought could not have added greatly to the force of the bare facts. He then detailed the population of the districts served by the hospital, pointing out that hospital accommodation sufficient for 218,000 persons—the number resident in the neighbourhood when the buildings were first planned—was clearly inadequate for 460,000, the present population.

The Marquis of LORNE moved: "That, recognising the great importance of the work of the West London Hospital to the community in the West London district, this meeting cordially recommends it to the sympathy and support of the benevolent on the ground that it performs a most useful work in an efficient and economical manner."

The resolution was seconded by Cardinal VAUGHAN, supported by Sir ALGERNON BORTHWICK, and carried unanimously.

Mr. HAYES FISHER moved the next resolution in place of Mr. Balfour: "That, having heard of the necessity of enlarging the West London Hospital, this meeting cordially approves the action of the board of management in proceeding with the erection of the proposed extension, and engages itself to support the undertaking by every means in its power."

Sir WILLIAM PRIESTLEY seconded the resolution.

Mr. STEPHEN PAGET, a member of the staff of the hospital, supported it, and explained the variety of the cases dealt with.

The resolution was unanimously carried.

The meeting concluded with a vote of thanks to the Duke and Duchess of Devonshire, moved by the Rev. the Hon. E. CARR GLYN, and seconded by Mr. L. ROTHSCHILD.

It was announced that subscriptions had been given or promised amounting to £1095.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5435 births and 3139 deaths were registered during the week ending June 8th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 17.7 to 17.2 per 1000, further fell last week to 15.5. In London the rate was 14.8 per 1000, while it averaged 15.9 in the thirty-two provincial towns. The lowest rates in these towns were 10.4 in Portsmouth, 11.3 in Croydon, 11.4 in Derby, 11.7 in Bradford, and 12.7 in Nottingham; the highest rates were 20.0 in Blackburn, 20.3 in Salford, 20.9 in Liverpool, 21.4 in Bolton, and 25.7 in Burnley. The 3139 deaths included 294 which were referred to the principal zymotic diseases, against 354 and 348 in the two preceding weeks; of these, 72 resulted from measles, 59 from diarrhoea, 51 from diphtheria, 51 from whooping-cough, 33 from scarlet fever, 28 from "fever" (principally enteric), and 2 from small-pox. No fatal case of any of these diseases occurred last

week in Croydon or in Halifax; in the other towns they caused the lowest death-rates in Sheffield, Newcastle-upon-Tyne, Leeds, and Sunderland, and the highest rates in Gateshead, West Ham, Plymouth, Salford, and Bolton. The greatest mortality from measles occurred in West Ham, Plymouth, and Bolton; from whooping-cough in Gateshead; and from "fever" in Burnley. The mortality from scarlet fever showed no marked excess in any of the large towns. The 51 deaths from diphtheria included 33 in London, 4 in Birmingham, 3 in West Ham, and 3 in Wolverhampton. One fatal case of small-pox was registered in Bolton and one in Oldham, but not one in London or in any other of the thirty-three large towns. There were 23 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 8th inst., against 27, 29, and 22 at the end of the three preceding weeks; 5 new cases were admitted during the week, against 4, 7, and 1 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1589, against 1446, 1503, and 1524 on the three preceding Saturdays; 179 new cases were admitted during the week, against 185, 214, and 187 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 245 and 193 in the two preceding weeks, further declined to 163 last week, and were 96 below the corrected average. The causes of 50, or 1.6 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Nottingham, Bradford, Newcastle-upon-Tyne, and in sixteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Huddersfield, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20.2 and 21.4 per 1000 in the two preceding weeks, declined again to 19.7 during the week ending June 8th, but was 4.4 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15.7 in Leith and 16.3 in Aberdeen to 21.8 in Greenock and 24.0 in Perth. The 567 deaths in these towns included 25 which were referred to diarrhoea, 12 to measles, 11 to whooping-cough, 4 to scarlet fever, 4 to "fever," 1 to diphtheria, and not one to small-pox. In all, 57 deaths resulted from these principal symtotic diseases, against 64 and 60 in the two preceding weeks. These 57 deaths were equal to an annual rate of 2.0 per 1000, which was 0.6 above the mean rate last week from the same diseases in the thirty-three large English towns. The 25 fatal cases of diarrhoea exceeded the number recorded in recent weeks, and included 11 in Glasgow, 4 in Edinburgh, and 4 in Paisley. The deaths referred to measles, which had declined from 30 to 12 in the four preceding weeks, were again 12 last week, of which 4 occurred in Glasgow and 3 in Greenock. The fatal cases of whooping-cough, which had been 17 in each of the two preceding weeks, declined to 11 last week, and included 6 in Glasgow. The deaths referred to different forms of "fever," which had been 5, 3, and 6 in the three preceding weeks, were 4 last week, of which 2 occurred in Glasgow, where 3 of the 4 fatal cases of scarlet fever were also recorded. The deaths from diseases of the respiratory organs in these towns, which had been 103 and 118 in the two preceding weeks, were 112 last week, and slightly exceeded the number in the corresponding week of last year. The causes of 30, or more than 5 per cent., of the deaths in these eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28.5 and 26.7 per 1000 in the two preceding weeks, further declined to 22.1 during the week ending June 8th, a lower rate than has been recorded in any week since November last. During the past ten weeks of the current quarter the death-rate in the city has averaged 28.9 per 1000, the rate during the same period being 17.1 in London and 19.1 in Edinburgh. The 148 deaths registered in Dublin during the week under notice showed a decline of 31 from the number in the preceding week, and included 11 which were referred to the principal symtotic diseases, against numbers

increasing from 5 to 9 in the three preceding weeks; of these, 4 resulted from diarrhoea, 3 from small-pox, 2 from whooping-cough, 2 from "fever," and not one either from measles, scarlet fever, or diphtheria. These 11 deaths were equal to an annual rate of 1.6 per 1000, the symtotic death-rate during the same period being 1.6 in London and 1.3 in Edinburgh. The fatal cases of small-pox, which had been 2 in each of the two preceding weeks, rose to 3 last week. The 4 deaths referred to diarrhoea showed a further increase upon the numbers recorded in recent weeks. The mortality from whooping-cough and from "fever" also exceeded that recorded in the preceding week. The 148 deaths registered in Dublin last week included 25 of infants under one year of age and 35 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a further decline from the numbers recorded in recent weeks. Twelve inquest cases and 4 deaths from violence were registered; and 51, or more than a third, of the deaths occurred in public institutions. The causes of 13, or nearly 9 per cent., of the deaths in the city last week were not certified.

SANITATION IN NEW JERSEY, U.S.A.

The State Board of Health of New Jersey, U.S.A., has since the publication of its seventeenth annual report suffered a loss which must, we fear, seriously affect its future. In the death of Dr. Ezra M. Hunt, the former secretary to the board, there has been removed the hand which to a large extent was instrumental in forming the board itself and which has in no small degree shaped its destinies from the date of its foundation eighteen years ago to the present time. The eighteenth annual report of the board, which is now before us, contains, side by side with the "In Memoriam," three able articles from his pen, one on Recent Sanitary Progress, another on Thoughts for Sanitary Workers, and the third an introduction to the Sixteenth Report of the Bureau of Vital Statistics. In the first of these articles Dr. Hunt refers largely to the recent contributions of English workers in sanitary science and to the reports of our Royal Commissions; and in dealing with the subject of cholera he remarks that the last International Conference in Paris "showed that no longer will we wait for this marauding pestilence to start forth on its mad mission; but that it, or the causes that produce it, will be attacked at the starting points, and thus our dealings with it will be far more radical and successful." Governments, he states, "are beginning to erect monuments or bestow other honours on their sanitary officers, and what was once patronised as a philanthropy is now held to be a necessary department of political economy, to be legislated for in the interests of the masses and for the welfare of all citizens." Dr. Hunt's executive duties have now fallen upon the shoulders of Dr. Henry Mitchell, who, in his secretarial report, deals in the main with administrative questions. He points out that one of the most useful functions of the central health authority is the investigation of epidemic outbreaks. Frequently, he observes, the source of infection is situated outside the jurisdiction of the local board in whose district the outbreak is chiefly manifesting itself. The present laws of the State, however, though they impose upon the State Board the duty of making such investigations, make no provision for the notification of outbreaks of infectious disease by the local boards. The effect of this is that the information with regard to the outbreak is often received in a casual manner and at a time when the difficulty of tracing its origin is very materially increased. The necessity for State interference has, Dr. Mitchell reports, been well illustrated during the year under review, when investigations into ten outbreaks revealed the fact that only in two instances were the local boards capable of dealing in any adequate degree with the epidemic; they could neither protect the neighbouring portion of the State nor their own citizens. The inquiries referred to have conclusively shown the urgent need for instant official notification from local boards to the State Board of Health. The difficulty of arranging the sanitary administration of large summer resorts is drawn attention to by Dr. Mitchell, and as an instance of this he mentions Jersey City, which in January has a population of some 200,000 and in July one of over a million; such sudden and extreme changes in population present most serious questions in relation to water-supply, sewerage, and scavenging. Among the epidemic outbreaks which took place in New Jersey in 1894, a subject dealt with by Dr. Clark

Hunt, we note two of enteric fever apparently due to the consumption of infected milk. In a paper on Diphtheria contributed by Dr. Daniel Strock a statement is made that "a well in proximity to a cesspool that receives the expectorated matter from a patient must be a menace to those who partake of its waters; and water-supplies that receive the sewage of cities and towns where the disease prevails are no doubt active factors in distributing the bacillus." This opinion will, we expect, hardly be accepted by English sanitarians, as no well-authenticated instance of the dissemination of diphtheria from polluted water has, as far as we are aware, been recorded in this country. Dr. Henry Colt contributes to the New Jersey report a very original and interesting paper on the Causation of Disease by Milk, in the introduction to which he remarks: "In the days of the Roman Empire it was the custom to accord to the noble infant civilian, with respect to his food, that which was his birthright; and the fabled and exceptional relation of Romulus and Remus to a lower mammal was the work of tradition. Two thousand years later this order is well-nigh reversed, and we sit in quiet complaisance and realise that as a result of the disastrous effect of civilisation upon human life a large and growing proportion of our race must needs be nourished by a domesticated lower mammal of the bovine species." From the report of the vital statistics for New Jersey we learn that among the counties of the State the general death-rate per 1000 for the year ended June 30th, 1894, ranged from 12.21 to 24.47, the total death-rate for the counties being 19.09. Among the cities of the State having populations above 5000 the rates range from 9.88 to 28.47.

PUBLIC HEALTH IN HONG-KONG.

The annual report of Colonial-Surgeon P. B. C. Ayres, C.M.G., on the work performed during 1893 in the different establishments in Hong-Kong under his supervision is an interesting volume, though a somewhat heterogeneous collection of matter, embracing as it does the reports of the Superintendent of the Government Civil Hospital and of the epidemic hulk *Hygeia*, as also those of the medical officer in charge of the gaol, the Superintendent of the Vaccine Institute, and the Government analyst. The report now before us has, the Colonial Surgeon observes, been delayed owing to the outbreak of plague, which, as we can well believe, taxed severely the energies of the administrative department. In reference to the operations of the Lock Hospital, Mr. Ayres reports that the return now submitted is the last he will be called upon to make owing to the fact that the Secretary of State has abolished the medical examination of women. For the last six years these examinations have been voluntary, and they seem to have been most highly appreciated by the women concerned, so much so, indeed, that at their request Mr. Ayres wrote to the Government pointing out that the women themselves had learned to value the benefits of examination and that they requested its continuance. This request, however, having been refused, the women suggested to the hospital nurse that if she would leave Government employ they would pay her a better salary and furnish a hospital containing rooms for her own private use, and they also proposed to the Colonial Surgeon that he should act as medical examiner. This certainly is very high testimony to the value of examination, and we can but offer our congratulations to the Colonial Surgeon on the tact with which the examinations and general control of the work must have been carried out. The institution has been carried on, Mr. Ayres observes, since 1858, twenty eight years under the Contagious Diseases Ordinance and six as a voluntarily attended venereal hospital for women. The Justices of the Peace have visited the hospital once a week and on no single occasion has a complaint been made. It seems hard, Mr. Ayres points out, that the wishes of the women should not be complied with, and that after forcing attendance upon them for twenty-eight years voluntary examination should be denied them; he regards it as a serious blow to the health of the colony. The Government analyst, Mr. Crow, has presented a report upon the practice among the Chinese community of injecting morphia hypodermically. It appears that some Chinamen came into hospital covered with innumerable puncture scars, and upon inquiry it was found that many small shopkeepers were administering hypodermic injections of morphia with the ostensible object of curing opium eating. The analyst procured samples of the solution used for injection and ascertained that at each injection half a grain of hydrochlorate of morphia was used.

Commencing with two injections per diem, the number was subsequently increased to four or five. We are glad to hear that an ordinance putting a stop to this practice was quickly passed. The Colonial Surgeon's report contains the answers furnished by the several officers at Hong-Kong to the queries presented to them by the Royal Commission on Opium. Dr. J. M. Atkinson, who for the last six years has acted as superintendent of the Government Civil Hospital, states that, as a result of his experience, he has arrived at the conclusion that neither opium nor alcohol when consumed by the Chinese and other native races in moderation is injurious. In answer to the query as to what would be the effect of cutting off the supply of Indian opium, the officials appear to be unanimously of opinion that supplies would be forthcoming from other sources. The Colonial Surgeon, for instance, observes: "Cut down the Indian opium so that it becomes unprocurable in China and too expensive in India, and China will grow opium sufficient for all eastern nations and Europe too if it can make a profit on it." In dealing with sanitation in Hong-Kong Mr. Ayres, after tracing the history of the colony in this matter since his arrival there in 1893, remarks "that many opportunities have been lost, notably after the great fire of 1872, when, to his disgust, the Colonial Surgeon saw the same old insanitary Chinese houses rebuilt more crowded than ever. At the moment of writing the terrible visitation of the plague has given the colony a very severe lesson, and a great opportunity, and there are hopes that the colony may become in the near future a model English settlement."

VITAL STATISTICS OF LONDON DURING MAY, 1895.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during May in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 6.8 per 1000 of the population, estimated at 4,392,346 persons in the middle of the current year. In the three preceding months the rates had been 5.9, 5.8, and 5.7 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in St. James Westminster, St. Martin-in-the-Fields, Strand, St. Luke, City of London, St. Saviour Southwark, and St. George Southwark; while they showed the largest excess in St. George-in-the-East, Limehouse, Poplar, Rotherhithe, Greenwich, Woolwich, and Plumstead. The prevalence of small-pox in London showed a further decline in May, 31 cases being notified during the month, including 8 in Lambeth, 6 in Rotherhithe, and 4 in Lee sanitary areas. The Metropolitan Asylum Hospitals contained 20 small-pox patients at the end of May, against 66, 54, and 34 at the end of the three preceding months; the weekly admissions averaged 5, against 15, 11, and 7 in the three preceding months. The prevalence of scarlet fever in London showed an increase upon that recorded in the preceding month; this disease was proportionally most prevalent in Chelsea, Stoke Newington, St. George-in-the-East, Bermondsey, Rotherhithe, Lambeth, Greenwich, Woolwich, Lee, and Plumstead sanitary areas. The Metropolitan Asylum Hospitals contained 1481 scarlet fever patients at the end of May, against 1569, 1485, and 1413 at the end of the three preceding months; the weekly admissions averaged 167, against 141, 145, and 152 in the three preceding months. The prevalence of diphtheria in London showed a further increase during May; among the various sanitary areas this disease showed the highest proportional prevalence in Whitechapel, St. George-in-the-East, Limehouse, Poplar, Rotherhithe, and Camberwell. There were 508 cases of diphtheria under treatment in the Metropolitan Asylum hospitals at the end of May, against 481, 435, and 430 at the end of the three preceding months; the weekly admissions averaged 81, against 50, 62, and 69 in the three preceding months. The prevalence of enteric fever in London showed a marked increase during the month under notice, owing principally to a severe outbreak in Plumstead; among the other sanitary areas of the Metropolis this disease showed the highest proportional prevalence in St. George Hanover-square, Clerkenwell, Greenwich, and Woolwich. Erysipelas was proportionally most prevalent in Kensington, Marylebone, St. Pancras, Bethnal-green, and Rotherhithe sanitary areas. The

MONTHLY ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON—MAY, 1895.

* Including deaths from membranous group.

* Including 37 cases of membranous group.

29 cases of puerperal fever notified during May included 3 in Lambeth and 2 each in Islington, Hackney, Poplar, Camberwell, Lee, and Plumstead sanitary areas.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various metropolitan sanitary areas, the deaths occurring in the institutions of London having been distributed among the different sanitary areas in which the patients had previously resided. During the five weeks ending Saturday, June 1st, the deaths of 6680 persons belonging to London were registered, equal to an annual rate of 15.9 per 1000 of the population, against 30.3, 30.0, and 18.3 in the three preceding months. The lowest death-rates during May in the various sanitary areas were 10.0 in Wandsworth, 10.4 in Lewisham (excluding Penge), 10.5 in Hampstead, 10.9 in Stoke Newington, 12.6 in Lee, and 13.1 in Hammersmith; the highest rates were 20.2 in Poplar, 20.3 in Strand, 20.5 in Newington, 20.8 in St. George Southwark and in Rotherhithe, 26.8 in Limehouse, and 29.5 in St. George-in-the-East. During the five weeks of May 730 deaths were referred to the principal zymotic diseases in London; of these, 194 resulted from measles, 183 from diphtheria, 169 from whooping-cough, 83 from diarrhoea, 64 from scarlet fever, 35 from enteric fever, 1 from ill-defined fever, and 1 from small-pox. These 730 deaths were equal to an annual rate of 1.7 per 1000, against 1.5 in each of the three preceding months. No fatal case of any of these diseases was registered during May in St. Martin-in-the-Fields; in the other sanitary areas the lowest zymotic death-rates were recorded in Westminster, Hampstead, St. Giles, Strand, Wandsworth, and Lee, and the highest rates in Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, and Rotherhithe. Only one fatal case of small-pox was registered in London during the month under notice, the corrected average in the corresponding periods of the ten preceding years being 29; this fatal case belonged to Rotherhithe sanitary area. The 194 deaths referred to measles were less than half the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Shoreditch, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, and Poplar. The 64 fatal cases of scarlet fever were 16 below the corrected average number; this disease showed the highest proportional fatality in St. George-in-the-East, Limehouse, and Rotherhithe sanitary areas. The 183 deaths referred to diphtheria exceeded by 43 the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Whitechapel, Limehouse, Mile End Old Town, Poplar, Rotherhithe, and Greenwich. The 169 fatal cases of whooping-cough were 136 below the corrected average number; this disease showed the highest proportional fatality in St. James Westminster, Shoreditch, St. George-in-the-East, Limehouse, St. George Southwark, and Bermondsey sanitary areas. The 35 deaths referred to enteric fever were 13 below the corrected average number; except in Plumstead, where this disease was epidemic during the month under notice, there was no marked excess of "fever" mortality in any of the sanitary areas of London. The 83 fatal cases of diarrhoea slightly exceeded the corrected average number. In conclusion, it may be stated that the mortality in London during May from these principal zymotic diseases was as much as 31 per cent. below the average.

Infant mortality in London during May, measured by the proportion of deaths under one year of age to registered births, was equal to 119 per 1000, and was below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. James Westminster, Hampstead, St. Martin-in-the-Fields, Bethnal Green, and Whitechapel; and the highest rates in St. George-in-the-East, Limehouse, St. Saviour Southwark, Newington, Bermondsey, and Woolwich.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-COLONEL O'DWYER has arrived at Halifax and taken over the duties of Principal Medical Officer from Surgeon-Colonel Archer. **Brigade-Surgeon-Lieutenant-Colonel Clapp**, retired pay, has been appointed to the Medical Charge at Pontefract. **Surgeon-Captain Clarkson** has been appointed to the Medical Charge of the Women's and Children's Hospital at Aldershot, in succession to Surgeon-Major Deane, whose term has expired. **Surgeon-Major**

Irvine has arrived in England on leave from Gibraltar, and **Surgeon-Captain Maher** from the West Coast of Africa on completion of a tour of service. **Surgeon-Captain Hale** has been transferred from the Eastern to the Western District, and **Surgeon-Lieutenant Dove** from Woolwich to the Home District.

ARMY MEDICAL STAFF.

Surgeon-Lieutenant-Colonel Alfred Henry Anthony, M.B., to be **Brigade-Surgeon-Lieutenant-Colonel**, vice **P. Le Feuvre Kilroy**, retired.

INDIA AND THE INDIAN MEDICAL SERVICES.

The following appointments are announced:—**Surgeon-Captain J. B. Jameson** to the Medical Charge of the 28th Bombay Infantry; **Surgeon-Major W. B. Browning** to be **Surgeon**, Second District, Madras; **Surgeon-Major F. C. Reeves** to be **District Medical and Sanitary Officer** and **Superintendent of Gaol, Madura**; **Surgeon-Captain H. S. Peeke**, A.M.S., to be **Staff Surgeon, Murree**; **Surgeon-Major J. Anderson**, Civil Surgeon, Bareilly, to hold Charge of the Central Prison, Bareilly, in addition to his other duties, until further orders; **Surgeon-Captain H. E. Drake-Brockman** (Bengal), on military duty, Nowgong, to the Medical Charge of the Bundelkhand Political Agency, in addition to his military duties, until further orders; **Surgeon-Lieutenant Hamilton**, doing temporary duty at the Native Hospital, Cawnpore, proceeds to Manipur, in the Assam District, for duty; the services of **Surgeon-Lieutenant W. Young** (Bengal) are placed temporarily at the disposal of the Government of the North-West Provinces and Oudh.

NAVAL MEDICAL SERVICE.

Surgeon and Agent H. R. Bramwell, M.B., at Tynemouth.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant John Parkinson Atkinson, M.D., 3rd Volunteer Battalion, the Suffolk Regiment, to be **Surgeon-Captain**.

VOLUNTEER CORPS.

Artillery: 1st Cumberland: **Surgeon-Lieutenant C. H. Powers** resigns his commission. **Rifle**: 6th Volunteer Battalion the Gordon Highlanders: **George Lyon**, M.B., to be **Surgeon-Lieutenant**. **Volunteer Infantry Brigades**: **Tay Brigade**: **Surgeon-Lieutenant-Colonel J. K. Anderson**, M.D., 2nd Volunteer Battalion the Black Watch (Royal Highlanders), is appointed **Brigade-Surgeon-Lieutenant-Colonel**.

THE FILTRATION OF DRINKING WATER.

Professor E. H. Hankin, the bacteriologist and chemical examiner with the Government of the North-West Provinces, India, who recently published a capital little pamphlet on the Bacteriological Test of the Purity of Water, which was noticed in *THE LANCET* of April 6th, has forwarded a communication to the *Pioneer Mail* of May 22nd on the purification of drinking water in India. **Professor Hankin** premises that he is not a water-drinker himself, and has no wish to encourage the habit in others. Ordinary domestic filters, he points out, are not only incapable of removing dangerous microbes from water, but are, on the contrary, to be regarded rather as a breeding-ground for them. The Pasteur-Chamberland and Berkefeldt filters, however, depending on a different principle to other domestic filters, have the power of removing nearly all the microbes from water when they are in working order. All dangerous microbes may be removed with certainty from water by boiling it for a short time. Some microbes are only destroyed by prolonged boiling, but these, so far as **Professor Hankin** knows, are completely harmless. Aerated waters are practically free from microbes if they have been kept for some time after being made. The gas under pressure kills the microbes—the cholera microbe in a few minutes, that of enteric fever perhaps only after a few days. The water of the large rivers in the North-West Provinces is safer to drink than the water from nearly all wells, the precaution being taken not to obtain it immediately below a town or during the rains, as it is, for obvious reasons, safer at other places and seasons of the year. Practically any dangerous microbe that gets into well water in the plains in the North-West Provinces gets there by direct human agency. If the well is properly covered in and the water raised by a pump this risk may be avoided. The good effect of such an arrangement is likely to be nullified if a filter is attached to the well or if any other open wells are left in the same compound. **Professor Hankin** is experimenting with potassium permanganate as a means of cleansing and disinfecting well water.

The results obtained by adding the substance, in the proportion of one ounce to an ordinary sized well, have been encouraging, though they are not sufficiently numerous for him to definitely recommend the practice as a sanitary precaution.

THE LATE SIR EDWARD HAMLEY.

The late General Hamley was a remarkable man in more ways than one. He was a gallant soldier who had distinguished himself by his valour in the Crimea, a strategist who had published a text-book on "The Operations of War" which has a European reputation, a brilliant writer and a novelist and essayist of no mean merit, and yet there can be no doubt that at the time of his death he was a disappointed man and laboured under a sense of wrong. With an unusual number of fine qualities he had an assertive and somewhat austere manner which probably led to his being misunderstood and misrepresented. The main cause of General Hamley's feeling of injustice and disappointment was connected with his services in command of the Second Division at the battle of Tel-el-Kebir, upon which fell, he alleged, the main burden and success of the assault. Mr. Shand, his biographer, who has written a very interesting account of Sir Edward Hamley's life, has gone fully into the subject, and the question which occupies the military mind at present is whether any explanation in the way of reply will be forthcoming. It is a subject that does not come within the province of medical journalism, and about which, of course, we are not competent to express any opinion, but our readers cannot have forgotten that an inquiry took place into the conduct of the medical service in the Egyptian campaign of 1882. Medical officers at the end of that expedition—in which better results had been obtained than had ever before been accomplished in the treatment of wounds and sickness in warfare—found themselves called upon to vindicate their department and its work on that occasion from what they thought unjust and ungenerous attacks. The result was not satisfactory to the medical service, and it was always understood that the late Sir Edward Hamley was no participator in the views of those who attacked it.

ARMY MEDICAL STAFF IN INDIA.

We are pleased to be assured by the Secretary of State for India (*vide* our Parliamentary Intelligence, p. 1555) that the establishment of the Army Medical Staff in India is considered sufficient for the requirements of the Army in peace and war, and that there is no reason to suppose that it is "terribly undermanned"; but this official answer to a question put by Mr. A. C. Morton does not at all dovetail with the following extract from a letter of an officer in India, recently published in the *Army and Navy Gazette*, on the condition of garrisons after the mobilisation of hospitals for the Chitral relief force had been carried out:—"The hospitals have been successfully mobilised for the expedition, but the result is that the stations are denuded of medical officers, chiefly those of the Indian Medical Service; all leave is stopped, and men are going sick with extra hard work. One medical officer is doing duty at the station hospital, is also staff surgeon, and, as well, in medical charge of a native cavalry regiment. Another is in charge of his own corps (a native regiment) and has to look after a large cantonment hospital as well. The Indian Government has no reserve for any emergency like the present. In fact, there is a paucity of medical officers, medical subordinates, hospital assistants, and ward orderlies, to carry on the medical duties of garrison hospitals."

THE LEE-MATFORD ARMY RIFLE.

Some doubt has been felt and expressed by military men as to the efficiency of the small new regulation projectile, used with cordite powder, to break the "rush" of an enemy on a line or square. A communication in the *Standard* of the 12th inst., in calling attention to this subject, quotes from a letter received from an officer engaged in the fighting at the Malakand Pass and at Khar during the recent Chitral expedition. Allowing for the fact that, as the writer does not appear to be a medical officer, his description may be inaccurate, the quotation is to the effect that a wounded Swati in one of the field hospitals was found to have had no less than six bullets through him—through the knee, ankle, trunk of the body, and one through the back of the neck, traversing the mouth, wounding the tongue, and carrying away two upper front teeth in its course. It is stated that the wounded man was able nevertheless to go voluntarily to the hospital for treat-

ment and was doing well. The correspondent of our contemporary asks whether such immunity from immediate disablement to an enemy does not mean greater danger and loss to our own soldiers when withstanding a charge or rush, such, for instance, as we experienced with the Arabs in the Soudan.

THE CHITRAL RELIEF FORCE.

According to the latest accounts, the health of the force—both European and native—is very good. The troops which composed Colonel Kelly's force have been suffering from the effects of their late exposure, severe marches, and the hardships they underwent. As we have already said, the fact that Colonel Kelly and his officers were comparatively unknown men in command of a small force of native soldiers and followers, is one of the most satisfactory things about the grand achievement they undertook and successfully accomplished. The enterprise, the fearlessness and courage of the leaders, and the pluck and endurance of the men who accomplished the work they set themselves to do are qualities of which we must all feel proud. The advance of the larger expedition under General Sir R. Low no doubt materially influenced the course of events and enabled Colonel Kelly's force to do what it did—namely, to make one of the most memorable marches on record. The description of this march from Gilgit to Chitral by the special correspondent of the *Times* is one of the most interesting narratives that has appeared for a long time.

INSPECTION OF THE VOLUNTEER MEDICAL STAFF CORPS.

The London Companies of the Volunteer Medical Staff Corps were inspected by the Duke and Duchess of Teck on Saturday, June 8th, when some 200 men paraded at Putney under the command of Surgeon-Colonel Norton. The smartness of the men, upon which they were complimented by the Duke of Teck, spoke well for the training they had received.

LEAVE FOR MEDICAL OFFICERS SERVING IN INDIA.

The *Pioneer Mail* of the 22nd ult. states that the Government of India have decided that leave out of India may now be granted to medical officers on the usual conditions—viz., if their services can be spared locally and with the consent of the Principal Medical Officer at headquarters.

Surgeon-Captain Michael Thomas Yarr, A.M.S., attached to the Coldstream Guards, has been appointed physician to the Crown Prince of Siam.

Correspondence.

"Audi alteram partem."

HOSPITAL SUNDAY.

To the Editors of THE LANCET.

SIRS.—For the twenty-fourth successive year the Council of the Hospital Sunday Fund—of which, in my official capacity as Lord Mayor, I am president and treasurer—have to claim your indulgence in drawing public attention to the approach of Hospital Sunday, and in invoking increased assistance for the medical charities of this great metropolis. The various congregations in the churches and chapels of London will have their attention drawn on Sunday next (Hospital Sunday) to the needs of these institutions and to the vast work which they are effecting among a population of over five millions, living close to each other, the majority of whom are poor, and many are sick, suffering, and dying.

Last year's statistics afford valuable testimony to the beneficent character of the operations of the hospitals and dispensaries of London. From these it is gathered that the voluntary hospitals and medical charities in the Metropolis relieved during 1894 no fewer than 1,383,000 patients at a cost of £699,527.

The ordinary income of the institutions amounted to only £559,725, leaving a deficiency on the year's work of £139,802. The number of beds in the hospitals is 8391, but only 6490 were occupied and nearly 2000 constantly remain empty for want of funds. The Hospital Sunday Fund distributed last year over £40,000 among ninety hospitals, twenty-two convalescent homes, thirteen cottage hospitals and fifty-four dispensaries, and in addition purchased surgical appliances for 2814 sufferers requiring that form of relief. The number of

contributing congregations was 1799, being the largest ever recorded in the fund's history, and representing every form of faith.

This year the Council venture once again to appeal for funds towards covering the deficiency of over £130,000 which remains when the ordinary income of the charities is exhausted. They feel that if this large sum is not actually raised by this one effort the benevolence of the public will, as in past years, materially supply the needs of the medical institutions. The value of the hospitals is not merely gauged by the amount of suffering relieved; it is within their walls that our medical practitioners acquire their skill, experience, and knowledge, that nurses receive their training, and the sanitation of our great city is improved and advanced.

On the religious aspect of the movement it is not for me to dwell. I would only say that it is an edifying sight on this annual recurrence of Hospital Sunday to witness people of all denominations and creeds sinking their differences and joining heartily in lending helping hands in the interests of the sick and suffering poor of this teeming city.

While it is desirable and conducive to convenience that intending donors should forward their contributions through their respective places of worship, I shall be glad to add to the fund any subscriptions which may be sent direct to me at the Mansion House.

Thanking you for the publicity which I feel sure you will accord to this appeal,

I am, Sirs, your obedient servant,
JOSEPH RENALS, Lord Mayor.

Mansion House, London, June 13th, 1895.

BATHING AND AURAL DISEASES.

To the Editors of THE LANCET.

SIRS,—As the bathing season is commencing it is not out of place to call attention to the fact that every year a number of patients are seen suffering from some aural disease which is directly attributable to bathing, especially sea-bathing. The most frequent troubles are acute otitis media, acute diffuse otitis externa, often associated with a ceruminous plug, a combination of the two preceding lighting up an acute condition in a chronic suppurative otitis media, simple deafness from swelling of a ceruminous plug, and occasional extension of a suppurative process to the antrum, mastoid process, &c. Other troubles from diving, such as concussion of the labyrinth, rupture of the membrana tympani, with subsequent acute otitis media, are occasionally seen; and there seems no doubt that sea-bathing is a cause of exostoses. The question as to how these may be avoided is an important one. It should be a rule that persons suffering from middle-ear discharge should never bathe at all, and those who have had middle-ear discharge and whose membranes have healed, or those who have any tendency to ear troubles, should never bathe without some efficient means for preventing water entering the ears, such as firm plugs of cotton wool with an oilskin cap fitting tightly over them as recommended by Dr. Urban Pritchard. Water remaining in the healthy ear should be let out as soon as possible; to effect this it is a good plan to incline the head well over to the affected side, straighten the meatus by pulling the auricle upwards and backwards, and execute a series of hops on the foot corresponding to the affected ear. The acute otitis seems to be occasionally caused by water which has entered the naso-pharynx being blown into the middle ear by the forcible efforts to expel it by the nose; this danger is of course greater if there is a nasal block present.

I am, Sirs, yours faithfully,
Harley-street, W., June 8th, 1895. ARTHUR H. CHEATLE.

THE "LIBERATOR" RELIEF FUND.

To the Editors of THE LANCET.

SIRS,—In accordance with a suggestion made by numerous sympathisers with the "Liberator" Relief Fund it is proposed to have a "Liberator" Sunday on the first Sunday in next month, July 7th, when the special claims and distressing need of the aged and destitute victims in this truly national and cruel disaster may be declared from every pulpit in the land, and all the worshippers present at least given an opportunity of contributing something. Many of whom may not be able to spare the time or may not think it worth while to send their small subscription by means of a postal order to the office of

the fund. We beg very heartily to commend the proposal to Christian Churches of all denominations, believing that if adopted to any general extent it would go far towards realising the much-needed augmentation of the fund, whilst affording a happy and striking illustration of the essential oneness of the various sections of the Christian Church in the work of Christ-like charity. The Executive Committee are now sending an earnest request for a collection, or part collection, to every clergyman and minister whose name and address they can procure, but lest they should fail to reach anyone who may be willing to join in this final endeavour to raise the Fund to the £100,000 required before it can relieve in any adequate sense the worst cases, we should greatly esteem if you would kindly give your valuable aid by calling attention to this special effort. We should like to add that a pamphlet has been prepared dealing at length with this matter, entitled "Liberator Victims: a First-charge on Christian Charity," copies of which, in any number desired, the Rev. J. Stockwell Watts, honorary secretary (16, Farringdon-street, E.C.), will be pleased to forward to clergymen or ministers willing to distribute the same among the members of their respective congregations.—Sincerely thanking you in advance for the kind insertion of this letter,

We are, Sirs, yours faithfully,
(Signed) KINNAIRD.

THE MEETING OF THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—I beg to call your attention to the report in your issue of the 8th inst. of the case of Mr. G. F. McCarthy on page 1470. By some oversight it is stated that "Dr. Braxton Hicks addressed the Council" &c. It is, no doubt, known to you that my father is Dr. J. Braxton Hicks, and in no way was concerned in the matter, and I should be glad if you will correct this in your next issue.

I am, Sirs, yours faithfully,
A. BRAXTON HICKS,
Lupus-street, W., June 8th, 1895. Coroner and Barrister-at-Law.

. We regret the oversight.—ED. L.

DEFECTS OF VISION AND ACCIDENTS.

To the Editors of THE LANCET.

SIRS,—This subject, I am sure you will agree with me, is worthy of notice in your journal. My knowledge of the question extends backwards to the year 1870. I was surgeon of the Cunard steamer *Russia*, and I had a unique experience in that capacity. The *Russia* was then a perfect steam-yacht, carrying no emigrants, and no member of the crew left her except through death or promotion. On one trip, during the muster prior to sailing, I detected a new member amongst the crew, and on looking at him carefully discovered that he had a glass eye. This set me thinking, and I made an examination of all the men who were on duty for that night, the result being that I discovered that the man on the opposite side of the bridge was also imperfect in his vision. These men were relieved from look-out duty. The following night, running down the Channel, we missed almost by a hair's breadth a collision with an East Indiaman. What would have been the result had these men with imperfect vision been on the look-out that night I do not know. *Ad vasa disce omnes*. That is the whole history of the origin of what I have done with reference to the question of defective vision as a cause of disaster at sea. In 1875 I wrote to you on this matter and you noticed my letter in an editorial paragraph. The matter was subsequently brought to the notice of the then President of the Board of Trade, Sir Thomas Grey, and was adopted by the

Cunard Company as an imperative law of their service. Recently an important deputation waited on the President of the Board of Trade on the subject. It seems to me that this deputation has fallen flat. I have personally written to the President, and have received simply an official recognition of the receipt of my document. And now, Sirs, it seems to me that the time is ripe for your powerful journal to take hold of this matter and insist upon one thing, the only remedy—namely, the appointment of a competent medical officer to the Board of Trade, who shall be able to render a full account of the competency of men who have charge of the lives of people at sea. I might prolong this matter further, but I believe this will suffice.

I am, Sirs, yours faithfully,
R. A. CALDWELL.

Sussex-place, Southampton, June 11th, 1895.

To the Editors of THE LANCET.

SIRS,—So many letters have appeared in THE LANCET recently on the subject of "Colour Vision and Accidents" that I think it may interest your readers to know that on the East Indian Railway—the largest undertaking in the East—every precaution is taken to safeguard the travelling public from any accident arising from colour blindness. The East Indian Railway has a medical department of its own, and the medical officers are responsible for the sight and colour vision of every candidate for employment who can in any way have anything to do with the working of trains or signals. For more than twelve years each candidate has had to pass the following tests in addition to the ordinary health examination: Holmgren's wools and army test dots by day, as well as being tested at night with a lamp specially designed for the purpose by Mr. H. H. Bathe, one of the company's medical officers. Both Europeans and natives must pass each test, and if their sight or colour vision is defective they cannot obtain employment. The test at night is very useful, as night blindness is very common in India. The lamp used is of excellent design and can be made to represent a signal at any distance. I have never known anyone who was colour-blind to distinguish correctly between green and red when the colours were alternated with rapidity. Mr. Beaumont, in your issue of April 20th, remarks that drivers can generally tell what the signals are by the difference in intensity, and goes on to say very truly that this is a most dangerous means of differentiating between green and red, as, owing to hurry or foggy weather, a man's train may be off the rails before he has made up his mind whether the signal is against him or in his favour. The lamp we use, representing as it does a signal, is a sure test for this kind of vision, as it can be turned from red to green with such rapidity that a man cannot pass unless his colour vision is perfect, and when taken together with the other tests forms a perfect safeguard. I may add that when a man is to be promoted or granted an extension of service such promotion or extension depends on his passing these tests of eyesight. Should he fall his career as a "running man" is at an end. I trust you will pardon the length of this letter, but the subject of colour vision is now so much discussed in England, and is one of such vast importance both to the public and to the railway authorities, if they would only realise it, that it seemed to me that a sketch of the actual working of correct tests for many years on a large railway in India might prove helpful.

I am, Sirs, yours faithfully,

J. STUART BROOKE.

District Medical Officer, East Indian Railway.

Amansol, Bengal, May 11th, 1895.

THE TREATMENT OF PSORIASIS.

To the Editors of THE LANCET.

SIRS,—Having been unavoidably absent from the Dermatological Society when Dr. Crocker read his paper, I am consoled by finding it published by you, especially as it contains support of the internal microbic nature of psoriasis. At the Birmingham meeting of the British Medical Association I read a paper on the Parasitical Nature of Psoriasis and its Treatment by Mercury,¹ in which I advocated this view on the grounds (amongst others) of its symmetry, the dilatation of the papillary vessels, and the utility of parasitocidal drugs, although there was not verification of Laug's epidermotophyton. Some evidence

of contagiousness was then adduced, and more has since been added. Salicin and the salicylates (which Dr. Crocker recommends), carbolic acid, the iodides, and arsenic are microbicides and can act in no other way. I am satisfied with that proven microbicidal measure, a mercurial course internally, or by inunction, or both combined. For twenty-five years I have treated psoriasis in no other way, and failures and recurrences having been very few, I regret it has not been extensively adopted by the profession. I may add that I have found no evidence of correlation between psoriasis and the rheumatic or any other diathesis.

I am, Sirs, yours truly,

E. D. MAPOTHER, M.D.

Cavendish-square, W., June 10th, 1895.

THE MEDICAL GUILD AT MANCHESTER AND THE INSURANCE OF CHILDREN.

To the Editors of THE LANCET.

SIRS,—With reference to the "Bill to amend the Law relating to the Insurance of Burial Expenses of Children" at present before Parliament, I am requested to send you the following resolution, passed at a meeting held on May 30th: "That in the opinion of the Council of the Medical Guild the most satisfactory check for the evils arising out of the insurance of children would be provided by enacting that it be required of all insurance companies and clubs, whenever a death claim is made and before it can be paid, to obtain in every case a medical certificate of the cause of death directly from the practitioner who attended the deceased during the last illness, and who certifies the cause of death for the purpose of registration." I am to add that, on the death of an insured child, it would be desirable to require of the insurance society with which it was insured to notify the fact of such insurance to the registrar of the district.

I am, Sirs, your obedient servant,

A. STEWART,

Hon. Secretary.

Manchester, June 4th, 1895.

"ADENOID GROWTHS IN CHILDREN."

To the Editors of THE LANCET.

SIRS,—I have to thank Dr. Eustace Smith for his kind and courteous reply to my questions. I am quite aware that adenoids are common in young children, and for this very reason we are not warranted in ascribing to them any symptom which is not relieved by their removal. I feel sure Dr. Smith will agree with me that the occurrence of some degree of adenoid hyperplasia in two cases of infantile respiratory spasm warrants no deductions as to cause and effect. I have referred to the paper by Dr. Robertson upon which Dr. Smith relies to establish his contention,¹ and cannot find that in any sense it corroborates the somewhat sweeping statements as to adenoids as a cause of infantile respiratory spasm, to which I took exception. If Dr. Smith will again refer to the paper he quotes, he will find that only one case can possibly be ascribed to adenoids. Even with regard to it, however, there is no definite statement to this effect, although it is mentioned that the "post-nasum" was scraped. In this very case inhalation of the larynx, nasal sprays, &c., were also employed. It is, therefore, incorrect to say that "cases" were described by Dr. Robertson proving the connexion between adenoids and infantile respiratory spasm, which I have ventured to doubt. I am very well acquainted with a form of pseudo-croup which owes its origin to adenoids in many cases, and in which the symptoms result from the naso-pharyngeal secretion falling into the larynx, and I am by no means satisfied that this single case, which may possibly support Dr. Smith's hypothesis, was not of this nature. In conclusion, I beg to assure Dr. Smith that it was no spirit of captious criticism which induced me to point out what I believe to be an error in his paper. There is in the present day such a great tendency to over-estimate the importance of limited regions of the body that every new symptom ascribed to such a region must be thoroughly proved before it can be accepted. Adenoid growths are most important in many respects, and it can only be pleasing to specialists to find a physician so justly eminent as Dr. Smith recognising their importance. We, however, find so many well-proved

¹ Brit. Med. Jour., Jan. 17th, 1891.

¹ Journal of Laryngology, 1891, p. 407.

symptoms to be due to this adenoid hyperplasia that we cannot afford to admit also those which rest upon pure hypobesias.

I am, Sirs, yours faithfully,
Chester-street, Edinburgh, June 10th, 1895. P. McBRIDE.

THE INFORMAL PURCHASE OF POISON.

To the Editors of THE LANCET.

SIRS,—No doubt you have, in common with many of your subscribers, read the correspondence going on the last few days in the *Standard* about the poisoning of dogs in Sussex. As one who was present and witnessed the horrid spectacle I found myself soon endeavouring to try to discover the perpetrator of the dastardly act, and while conversing with a well-known Sussex veterinary surgeon he told me the following anecdote. A veterinary surgeon practising in this country was recently ill; during his illness a hamper of drugs arrived at his house, but was not meant for him. It was addressed Mr. So-and-so, Veterinary Surgeon. As he was the only member of that profession for miles round it was delivered to him. He recognised the name of the man for whom it was meant. On examining the invoice an ounce of strychnine was found charged for. Therefore the veterinary surgeon wrote to the druggists explaining all the circumstances and asking if they still wished him to send on the hamper with so much poison in it. To this they replied with no little asperity that it was no business of his to meddle with other people's invoices, and he must send on the "goods" at once. They further added that they always executed prepaid orders to anyone who desired them to do so, which is the custom of the trade.

Now, Sirs, if this is so, no wonder that keepers and others can get what poisons they want without troubling the local druggists or going through the formality of signing poison-books. Some stringent measures will have to be taken to prevent a dire calamity from happening some day.

I am, Sirs, your obedient servant,
Brighton, June 7th, 1895. A BRIGHTON SURGEON.

THE BOYLE LECTURE AT OXFORD.

To the Editors of THE LANCET.

SIRS,—Being stone deaf, and—so far as the medical and surgical science and skill of the present day extend—apparently hopelessly so, everything that tends towards the elucidation of the structure and functions of that little understood region, the inner ear, possesses for me an exceptional interest. Professor Crum Brown is reported in a recent lecture to have said that he looked upon the semi-circular canals as constituting a special hydrodynamical mechanism for regulating (amongst other things!) the compensatory movement of the eyes. "When the head is moved rapidly in one direction the eyes have to move to a corresponding extent; this movement is carried on by a series of small jerks with pauses between them. The same phenomena are produced when the head is rotated on an antero-posterior axis. In seeking for the cause of this compensatory action of the eyes Professor Crum Brown comes to the conclusion that we have in the semi-circular canals a perfectly definite sense organ, which acts by the increase of pressure induced by movement of the head in the membranous ampullæ; the stretching of the ampullary walls by the fluid irritates the nerve endings in the crista acustica." Now, if the above may be taken as a correct rendering of the Professor's theory, I venture to think that the latter is open to criticism on more points than one. In the first place, Do the eyes really have to move to a corresponding extent while the head is going through the motions that are commonly regarded as expressive of negation and assent? Evidently not necessarily so. Any person can prove for himself by simple experiment that his eyes may remain fixed on any object during both processes. All he has to do is to exercise his will to that end. Secondly, the ampullary walls must be just as much subjected to increase of pressure during head movement whether the eyes remain fixed on an object or exhibit compensatory action. What, then, in the former case becomes of the irritation of the nerve endings in the crista acustica? Why should increase of pressure acting upon a perfectly definite sense organ excite compensatory eye movement in the one instance and not in the other? In my humble opinion these unanswerable questions invalidate the whole theory, but of course I am open to enlightenment and

correction. The answer to my objections may be as plain as a pikestaff to anyone thoroughly acquainted with Professor Crum Brown's theory; but failing additional data I am unable to pick it out, and hence my desire to read the unabridged lecture. As regards the series of small jerks by means whereof the apparently smooth movements of the eyes are carried on, I would merely beg leave to inquire whether this is not the usual procedure—whether all muscular motion is not carried on by means of series of small jerks, with pauses between them, for all the world like Mrs. Jarley's waxworks on a miniature scale? Such has always been my impression, but I cannot recall the source of origin, or, to be perfectly accurate, it does not seem worth while trying to do so. Finally, what would small jerks be like if there were no pauses between them?

I am, Sirs, yours faithfully,

SURDUS.

** Our correspondent will find the lecture reported in full in our issue of May 25th.—ED. L.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Birmingham Medical Benevolent Society.

THE seventy-fifth annual meeting of this society was held on the 7th inst. under the presidency of Mr. Priestley Smith. The report stated that the directors were able to speak with satisfaction on the work done during the past year. The invested funds amounted to nearly £12,000. The annual value of grants ranged from £20 to £40. The total sum distributed during the year had been £550. The total number of benefit members was 306. Seventeen new members had joined in the year. The usual votes of thanks were passed, and a number of the members dined together afterwards. Some interest is felt in the management of this society owing to the conservative tendencies of the directorate. It is considered by some that a larger amount ought to be available for distribution, and that the invested sum is too high for carrying out the real objects of the founders. No doubt a wider and more liberal basis of benevolence would tend not only to a greater good to a larger number of beneficiaries, but would be calculated to extend the number of the members, the proportion of whom to the number practising in the district being lamentably small.

Milk Adulterated with "Splash."

A dairy company was recently fined at the local police-court to the tune of £10 for selling milk with 19 per cent. of added water. The company's servant stated that the manager had ordered him when he fetched the milk from the farm to take some "splash" with him and put it into the milk. He also put water with the milk on another date. The tricks of the trade in this instance were properly rewarded by the penalty named, which renders this mode of conducting business somewhat expensive.

Sutton Coldfield and the proposed Sanatorium.

In a previous communication it was mentioned that the offer of the Royal Hotel at Sutton Coldfield as a sanatorium had been generously made by Colonel Wilkinson. It seems that certain of the inhabitants of the town have met to express their strong disapprobation of the scheme. A deputation was formed to confer with the donor as to the circumstances as affecting the locality, much alarm being felt that it would seriously affect the future welfare of the borough. It is to be hoped that the exclusiveness of these particular inhabitants will not prevent the execution of this admirable gift.

Lady Factory Inspector at Work.

In a case involving four summonses Miss Deane, one of Her Majesty's lady inspectors of workshops, prosecuted, with the result that fines were imposed of 20s. in one case with costs, 10s. and costs in another, and costs in the remaining two cases. The girls employed were kept until ten and eleven o'clock at night, the proper time for leaving being eight o'clock. The frequent plea of inadvertence was vainly argued, and the law asserted its power—a warning not without its value in a large city with numerous workshops of a similar kind.

Hospital Saturday.

The total amount paid into the bank this year has been

£12,447 15s. 9d., as compared with £11,794 10s. 11d. last year—a very creditable and satisfactory result for all concerned, in spite of the croakings of bad trade and foreign competition so constantly urged.

June 12th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Victoria University: Conferring of Honorary Degrees.

AN interesting ceremony took place on the 30th ult. at the Owens College. For the first time in its history the Victoria University exercised the privilege of conferring honorary degrees. The day's proceedings opened with a special meeting of the Court of Governors, under the presidency of Earl Spencer, K.G., the Chancellor of the University, who moved, and it was resolved unanimously, to confirm the degree of Doctor of Laws in the Victoria University already conferred upon his Grace the Duke of Devonshire, K.G., President of the Owens College, and the Right Hon. the Earl of Derby, G.C.B., President of University College, Liverpool; and on the further motion of the Chancellor it was further resolved to admit the following noblemen and gentlemen to honorary degrees: The Most Hon. the Marquis of Ripon, K.G., President of the Yorkshire College, to the honorary degree of Doctor of Laws; the Right Hon. Lord Kelvin, President of the Royal Society, to the honorary degree of Doctor of Science; the Right Hon. James Bryce, M.P., to the honorary degree of Doctor of Letters; Sir Andrew Fairbairn to the honorary degree of Doctor of Science; Sir Henry Roscoe, M.P., F.R.S., to the honorary degree of Doctor of Science; Mr. Thomas Ashton, to the honorary degree of Doctor of Laws; Mr. Richard Copley Christie, to the honorary degree of Doctor of Laws; Mr. William Rathbone, M.P., to the honorary degree of Doctor of Laws; Professor Arthur W. Rucker, F.R.S., to the honorary degree of Doctor of Science; Mr. Alfred Waterhouse, R.A., to the honorary degree of Doctor of Laws; Professor Adolphus William Ward, Vice-Chancellor and Principal of the Owens College, to the honorary degree of Doctor of Letters; Professor Gerald Henry Randall, Pro-Vice-Chancellor and Principal of University College, to the honorary degree of Doctor of Letters; Professor Nathan Bodington, Chairman of the Board of Studies and Principal of the Yorkshire College, to the honorary degree of Doctor of Letters; Professor Daniel John Leech, M.D., F.R.C.P., Chairman of Convocation, to the honorary degree of Doctor of Science; and Mr. Alfred T. Bentley, Registrar of the University, to the honorary degree of Master of Arts. Later in the day the degrees were conferred in the Chemical Theatre, which had been adapted for the purpose of the ceremony by the erection of a dais running the whole breadth of the room, redeeming it somewhat from its usual well-like aspect. A large hall, suitable for such ceremonies and other large gatherings, is one of the wants of the College. The lower part of the theatre was filled with the invited guests of the University, among whom, by the way, men were rare, their absence, from a picturesque point of view, being more than compensated by the greater brilliancy given to the scene by the gay toilets of the ladies. On the benches above were the graduates, several of whom were ladies, wearing the academical costume of gown and hood. The highest benches were occupied by the undergraduates of the College, who entered, as the *Manchester Guardian* puts it, "like a reservoir that has broken its dam," but were, on the whole, marvellously well behaved. Owing to a family bereavement, Mr. Thomas Ashton and his son-in-law, Mr. Bryce, M.P., were unable to be present. In the evening Earl Spencer and other guests were entertained to dinner at the Queen's Hotel by the members of Convocation. Dr. Leech, Chairman of Convocation, presided, and amongst those present were the Marquis of Ripon, Lord Kelvin, Sir H. Roscoe, Mr. William Rathbone, M.P., Sir A. Fairbairn, Mr. R. O. Christie, Sir B. T. Leech, Alderman Joseph Thompson, Sir Charles Halle, Dr. Ward (Vice-Chancellor), Dr. Randall (Principal, University College, Liverpool), Principal Bodington (Leeds), Mr. Charles Hughes, Professors Wilkins, Dawkins, Young, Tout, Sinclair, Dreschfeld, Schuster, Jones, Smithells, Kastner, Seaton, Reynolds, Ferkin, and Stirling; Mr. E. S. Heywood, Mr. J. E. King, Mr. Henry Wilde, Dr. Caton, Mr. A. T. Bentley (Registrar), and Mr. A. H. Worthington.

"Dr. Niven on Jewish Mortality."

I regret the occurrence of any errors in the notice of

Dr. Niven's remarks on the mortality of the Jews in Manchester. It was taken from the reports in the local papers, which must have been inaccurate; but, so far as I have observed, no correction of those reports has been made.

Visit of the Shahzada.

Manchester has been interested to-day in the visit of the Shahzada, who has been received with all the hospitality the Lord Mayor and corporation have been able to give. He has had the opportunity of seeing some of the poorer parts of Manchester, occupied almost entirely by the working classes, and it would be interesting to know what impression was made on the Oriental mind by the sight of hundreds of cotton operatives of both sexes in their ordinary working attire. The work of the day began soon after ten by the inspection of a large cotton mill in Ancoats. In London it has been said that he is listless, but it has not been so here. He was thoroughly interested in the various stages of cotton spinning, from the raw material to the finished thread, and was so much engrossed in the various processes that he seemed the last to wish to leave. On being asked if he cared to see some large engines at a neighbouring mill he said he would like to do so, although his decision deprived him of the pleasure of seeing a crowd of merchants and manufacturers at the Exchange, where a visit had been intended. These engines are of 800 and 600 horse-power respectively, and the Shahzada showed the most intelligent interest, immediately asking for information about them. In this visit he was accompanied by the Lord Mayor, Sir Joseph Leese, M.P., the Recorder, and Mr. Talbot, the town clerk, and three or four of the aldermen of the city, together with the members of his suite and Colonel Talbot, who acts as interpreter. From the mills the *cortège* drove slowly through the streets, where crowds of people were waiting to obtain a glimpse of the Prince, to the town hall, where an address was presented to him. His reply, which seemed to be spontaneous, was very cordial, and, when translated by Colonel Talbot, elicited hearty applause. The Lady Mayoress was then presented to his Highness, and also Sir J. Harwood, after which the mayors of some twenty neighbouring towns, decorated with their gold chains of office, shook hands with the Prince. He was afterwards entertained to luncheon in the large hall. The members of the council and invited guests numbered about 250. Many ladies were present when he received the address. The last item in the day's programme was a visit to the Ship Canal. Leaving the town hall soon after three, the Shahzada, with his suite and a number of other gentlemen, embarked on the canal at the Pomona Dock and sailed down as far as Irlam Locks. From Irlam a special train was to take them to Liverpool. This is a pretty good day's work, and it must be hoped that the last part of it will not try the endurance of his Highness too much, for the dry hot weather we have had lately has brought the smell, or rather the stench, of the canal to a pitch rarely, if ever, surpassed. If not impressed with the greatness of this engineering work, he will surely bear away a lasting recollection of the odour with which he was regaled. He has been said to look bored and apathetic, but was evidently moved on hearing the volume of sound from the fine organ in the hall, when Mr. Pyne (a cousin, by the way, of Sir Salter Pyne, who is high in the confidence of the Ameer) played "God Save the Queen," and he also seemed to enjoy smoking cigarettes at the conclusion of luncheon.

Theses for the M.D. Degree, Victoria.

The dissertations of the following candidates have been approved by the Council as qualifying for the degree of M.D.:—(1) A. J. Edwards, M.B., on "Disseminated Sclerosis"; (2) W. J. Kerr, M.B., on "The Effects of Alcohol on the Liver"; (3) Frank Robinson, M.B., on "A Clinical Record of 200 Cases of Small-pox"; (4) W. W. Stoney, M.B., on "Ophthalmic Goitre"; (5) R. T. Turner, M.B., on "Infantile Paralysis resulting from Cerebral Disease." The dissertations of A. J. Edwards and W. J. Kerr are highly commended, and the dissertation of W. W. Stoney is commended.

June 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Temporary Hospital in Edinburgh.

THE public health authorities in Edinburgh have had it intimated to them by the Board of Works that it is time they

should remove the temporary hospital erected in the Queen's Park during the small-pox epidemic last year. The erection of the hospital was much objected to at the time, and the citizens will be glad when it has ceased to exist. The authorities, however, propose to delay its removal until it is assured that small-pox has definitely disappeared.

Professor Annandale.

Professor Annandale's numerous friends and old students will be sorry to know that he has been in such indifferent health that he has not been able to attend to his professorial and hospital work for some weeks. He is, however, progressing satisfactorily.

Glasgow Royal Infirmary.

The managers have recently for the first time acted upon their resolution to terminate the appointment of physician or surgeon to the infirmary at the end of ten years. Apart from the hardship this entails upon individuals it may be questioned whether the policy is a wise one from the point of view of the hospital itself. The position of a hospital physician or surgeon ought certainly to be conferred only on those who have trained themselves carefully in the junior and subordinate positions. This means years of tedious and unremunerated work. If at the end of this a short ten years is to be the full time permitted for the more dignified and, in an indirect way, better remunerated positions, younger men may well pause before they deny themselves the more rapid successes of private practice for the sake of cultivating an efficient hospital training. It will certainly be impossible to get men to devote themselves entirely to medicine or surgery, as the case may be, if only so brief a prospect of establishing a definite position is permitted to them.

Medical Evidence in Criminal Cases.

There has been for some time amongst a section of the profession a feeling of dissatisfaction with the regulations which govern the preparation of the medical evidence in murder cases and in other cases involving a post-mortem examination for legal purposes. Under the present system this examination is made by the two medical men appointed by the Crown, and their report is submitted in court as evidence, they themselves being present to support it in the witness-box and to undergo the ordeal of cross-examination. But no attendance of a medical man in the interests of the accused is permitted at the post-mortem examination. This, it is claimed, is unfair, or may be unfair, to an accused or suspected person. On the other hand, it is answered that the Crown representatives are quite independent, and have no temptation to be anything but impartial, whilst the representative of a prisoner must necessarily, in order to justify his existence, endeavour to strain everything in his client's favour. Doubtless the advantages are not altogether on the one side, but it would certainly remove all semblance of unfairness, and be more in harmony with modern practice, to allow the prisoner to have a medical representative at the post-mortem examination; the theories of the defence would of course be subject to examination in open court, and could thus, if necessary, be discredited. And, further, it is difficult to believe that every man appointed by the Crown to be an examiner for medico-legal purposes can successfully resist the bias which the position suggests. Those who are advocating a change in the present practice have brought the question before the highest legal officials, and from a recent answer given by the Lord Advocate to a question put to him in the House of Commons it was supposed that on application a medical man would be permitted to represent an accused person at any post-mortem examination made by the Crown officials. This impression seems to have been unwarranted, as the application of a prisoner at present lying under a charge of wife murder to be thus represented has just been refused by the Crown. It is probable, therefore, that some further movement may be expected in the matter.

Medical Appointment.

Dr. Maxwell Ross, Dumfries, has been appointed medical officer for the burgh of Moffat in the room of Dr. Grange, who recently resigned.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Workhouse Scandal.

THE Irish Medical Association recently addressed a circular letter to the medical officers of the unions in Ireland asking

for definite information as to the condition and wants of workhouses and workhouse infirmaries. Seventy-nine of these gentlemen supplied the required information, while others declined to do so on the ground that they feared to incur the hostility of their respective boards. The replies have been carefully analysed and compared, the result being a series of grave reflections on the administration of many of the Irish workhouses. The matter has now been made public by a letter addressed to THE LANCET and other journals by Sir Philip Smyly and Mr. Hepburn, the chairman and hon. secretary of the Association. From their statement it appears that "forty-three of the infirmaries have no trained nurses, the nursing being left altogether in the hands of pauper women, in fifty-nine there is an absence of all sanitary arrangements, and in forty-three there are neither plates, knives, nor forks." These statements, upon which you commented last week, seem almost incredible, and one is not surprised to see in the press a challenge to the Medical Association to make public at once the names of the unions in which the sanitary arrangements are as described, and of those in which the inmates are not allowed the use of plates or knives and forks.

Irish Representation on the General Medical Council.

It was the good fortune of Dublin to have on the occasion of the recent meeting of the General Medical Council a very full representation, for, in addition to Sir John Banks, Sir Philip Smyly, Dr. Atthill, and Dr. Moore, Dr. Haughton of Trinity College happily found himself strong enough for the journey to London and for the heavy work of the session. Dr. Atthill and Dr. Moore have been working on the Pharmacopœia Committee.

St Michael's Hospital, Kingstown.

Mr. L. Halligan, L.R.C.S., L.R.C.P. Irel., has been appointed resident medical officer to the above hospital for the ensuing year.

Death of Dr. Robert Kerr Johnston of Dublin.

On Saturday, June 1st, the remains of the late Dr. Robert K. Johnston were removed from his residence, 22 Lower Baggot-street, for interment at Mount Jerome Cemetery. The deceased gentleman, whose funeral was largely attended, was most popular in his profession and amongst all classes in Dublin. His demise at such a comparatively early age has caused a widespread feeling of sympathy with his relatives. Dr. Johnston obtained the degree of M.D. in 1885 and was a most distinguished graduate of Dublin University as well as a Senior Moderator and Gold Medallist in Experimental Science. He filled for some years the office of ophthalmic surgeon to Dr. Stevens' Hospital, and was assistant surgeon to the National Eye and Ear Infirmary.

The Irish Medical Association and the Poor-law Officers' Superannuation Bill.

The annual meeting of the Irish Medical Association took place on the 3rd inst. at the Royal College of Surgeons in Ireland, Sir William Sticker, the new president, being in the chair. The report of the delegates deputed by the association to further in Parliament the Poor-law Officers' Superannuation Bill contained a statement, *inter alia*, that all their efforts to induce members of the National Federation party to undertake the task of introducing the measure and watching its progress in the House had failed. Mr. T. W. Russell, M.P., to whom the thanks of the association are due, ultimately undertook the work and introduced the Bill, only to see it peremptorily stopped at its second reading. The delegates now report that they can entertain no hope that the Bill will ever pass unless after discussion as an opposed measure. Under these circumstances the council of the association resolved to consult all the Poor-law medical officers of Ireland as to the advisability of advocating the extension of the English "Bill to provide Superannuation for Poor-law Medical Officers" to Ireland. That measure, introduced in last February, proposes that in return for a percentage contribution from their salaries every Poor-law officer shall be entitled to a superannuation allowance when he becomes incapable of discharging the duties of his office. The council, taking into consideration the probability of its passing, have consulted the medical men in Ireland who are most interested in the matter, with the following result: to 1119 circulars sent out there were 622 replies, which included 423 ayes, 184 noes, and 15 spoiled votes. The Poor-law medical officers of Ireland have therefore, by a substantial majority, pronounced themselves in favour of an extension of the "percentage contribution system" to this country.

Fire in a Medical Man's House.

A fire, involving the loss of some valuable property, took place on the 10th inst. at the residence in Dublin of Surgeon-Lieutenant-Colonel Holmes, who holds an appointment at the Royal Infirmary. The upper rooms of the house were entirely destroyed and several articles of vertu, gold and silver coins from India, &c. were found buried in the ashes.

Society for the Prevention of Cruelty to Children.

On Thursday, June 6th, the annual meeting of the Belfast branch of this society was held. It was reported that during the past year 816 cases were investigated, of which 796 were found to be well founded. These cases involved the welfare of 2396 children. Reference was made at the meeting to the help given by the city coroner, Mr. Finnigan, to the society, and especially to his manly stand on the question of the insurance of children.

Quadruple Birth.

On June 9th a poor woman in the dispensary practice of Mr. Irvine of Ballyhalkamore, Belfast, gave birth to four children; one lived for an hour, and the other three were still-born.

Proposed Museum for Bangor, co. Down.

I understand that Captain John Johnstone, superintendent of the Johnstone Steamship Company, Liverpool, himself a native of Bangor, co. Down, has offered to present to the place of his birth his valuable museum, which is claimed to be one of the finest private collections in the kingdom. It comprises natural history objects, bric-a-brac, ancient weapons, coins, an Egyptian sarcophagus, &c. At a meeting of the inhabitants of Bangor, held on June 7th, it was decided to convey their thanks to Captain Johnstone and to accept his most generous offer. Captain Johnstone will also defray the cost of transit of his museum, and will give a subscription towards a hall. It is thought the present would be a good time to build a town hall in which the museum, library, &c. could be located and which would be a most useful addition to a seaside resort visited by so many Ulster people.

Strangford Lough Boating Accident.

On June 8th the body of another of those drowned on April 11th (Miss Fanny Cheshire, Lady Kathleen Cole's maid) was picked up in the lough at Prieststown, near Portaferry. Of the eight drowned three have now been recovered, so that five bodies are still missing.

Downpatrick Water-supply.

At a meeting of the Downpatrick board of guardians held on June 8th Mr. Olpherts, medical officer of health, reported that, the new water-supply having failed, it would take months (perhaps years) before they could obtain a safe drinking water. The storage reservoir holds a very few days' supply now that it is used for flushing purposes. He says there are nine or ten streets without any supply, one street with a supply unfit for use, and three streets with a scanty supply. The public supply would long since have failed but for the kindness of those who have private pumps. He urges the sanitary authorities to bestir themselves in the face of a water famine. The town now gets its supply mainly from pumps.

A Rector's Bravery Rewarded.

Before the commencement of the ordinary business of the Petty Sessions Court at Tralee last week a very interesting function took place. Mr. Lynch, R.M., presented the medal of the Royal Humane Society to the Venerable Archdeacon Orpen, Rector of Tralee, for conspicuous bravery in saving the life of a boy who had fallen into the canal. The magistrate in making the presentation briefly explained that the Archdeacon, finding the lad was in imminent danger, waited only to divest himself of his great coat, and then plunged in at considerable personal risk. All who had witnessed the rescue were loud in praise of the promptness and pluck exhibited by the rector. Archdeacon Orpen on receiving the medal was greeted with loud applause.

Sad Deaths of Two Brothers from Sunstroke.

The weather in Cork has recently been very hot, and headache has been rather a prevailing complaint. I regret to say that two very distressing cases of sunstroke occurred in the course of last week in the neighbourhood of the city. A boy fourteen years of age, on arriving home from school last Tuesday evening, complained of dizziness and pain in his head. Surgeon-Colonel O'Connell, stationed at Ballincollig, was requested to visit him, and pronounced it to be a case of sunstroke. In spite of assiduous care the lad sank rapidly

and died within about twenty-four hours of the commencement of the attack. A few days later a brother of the deceased, only thirteen years old, was also affected by sunstroke, and survived only some eight or ten hours.

An Entertaining American.

A lady doctor, who states she obtained a medical degree in America, has recently delivered a course of lectures for women in Cork. She made no charge for admission to the first few lectures, but when her subject was "Maternity" payment was demanded at the door. A book entitled "Discourses to Women on Medical Subjects" was on sale at all the meetings, while a *séance* was held every day at the lecturer's residence. She was also ready to sell pessaries and give advice and medicine at fees which seemed to the professional mind out of proportion to the value of her services. In my humble judgment those of the Cork matrons and maids who patronised the lecturer would have shown more prudence by remaining at home and attending to their domestic duties.

June 11th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Suicide in France.

STATISTICS relating to suicides &c. are issued tardily in this country of red tape; it will, therefore, not surprise your readers if I am able to give them in this year of grace, 1895, the figures of 1892. It would appear that the number of suicides, after having diminished in 1889 and 1890, became more considerable during the two succeeding years. In 1880 there occurred 6638 self-destructions; in 1891, 8884; and in 1892, 9285. Minors appear to have every year more frequent recourse to this tragic method of terminating their real or supposed miseries. Thus, in 1892, 87 individuals under sixteen committed suicide, the corresponding figures for 1880 being 55, and for 1890, 80. The number of suicides between the ages of sixteen and twenty-one was for 1880, 267; for 1890, 358; and for 1892, 475. If my memory does not play me false, Alphonse Daudet, whose recent visit to England has excited so much interest, ascribed long ago in his novel, "Froment jeune et Rialor aîné," the greater frequency of suicide in modern Paris to the growing prevalence of unbelief amongst the young. I for one believe him to be right.

The Prophylactic Properties of Anti-tetanic Serum.

M. Vaillard¹ has rendered useful service in reminding the profession of the marked prophylactic properties of anti-tetanic serum employed hypodermically. The serum is now acknowledged to be powerless to counteract the virus once the disease is declared in an acute form. When, however, the evolution of the tetanus is slow, the injections, associated with removal of the tissues primarily inoculated, increase the chances of recovery. But it is as a prophylactic agent that the value of the serum is conspicuous. Injected into animals it renders them quite immune against the toxine. This immunity is only temporary, lasting from two to six weeks, according to the dose employed. But successive injections may be had recourse to without inconvenience. Certain and complete immunity is further conferred on animals into whose areolar tissue the virus has been introduced, but a like happy result cannot be predicted with certainty when the poison has been introduced into the thickness of a muscle. This is explicable enough when one considers that it is to phagocytosis that we must look for the successful destruction of the virus, and that this process is always rudimentary in the muscle, whereas in the subcutaneous tissue it is most active. The injection of the serum as a preservative is, therefore, called for in individuals who have met with traumatism which, from their situation, their nature, and the circumstances attending their infliction, are known commonly to lead to tetanus (contused wounds contaminated with soil, dust, dung, or river mud; wounds complicated with entrance of foreign bodies that have been in contact with the soil). The employment of the serum is again indicated in animals that have undergone operation known to favour the *éclosion* of tetanus (castration, tail-amputation, and operations on the hoof). M. Vaillard tells us that the preventive use of the serum is destined to render immense services to the inhabitants of

¹ Académie des Sciences, May 27th.

tropical countries, where tetanus is so apt to supervene on trivial injuries as to constitute one of the principal causes of death amongst the natives. The serum will be specially applicable in certain northern countries of Europe where tetanus of the new-born is responsible for as much as 60 per cent. of infant mortality. Again, what a prospect of salvation does the employment of the method hold out in military surgery in time of war. In veterinary practice thousands of valuable lives may thus be saved. Already Professor Nocard has inaugurated this preventive treatment, and the injections have been in the hands of several veterinary surgeons the means of arresting the disease after such operations as castrations and such injuries as penetration of a nail into the hoof. Who would, twenty years ago, have prophesied that tetanus would be converted into what it actually is—a preventable disease?

Butcher's Meat.

The regulations best calculated to protect the public against the sale of tainted meat were the object of discussion at some recent meetings of the Académie de Médecine. They culminated in the adoption of the following resolution, formulated by Professor Nocard: "Toute viande destinée à l'alimentation publique ne peut être mise en vente et colportée que pourvue d'une estampille (stamp) prouvant qu'elle a été reconnue saine par un inspecteur compétent; l'inspection doit être faite partout, dans les villages comme dans les villes; on peut l'organiser aisément et à peu de frais sur des bases analogues à celles qui sont adoptées en Belgique."

June 11th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Mellage Trial.

SHOCKING revelations concerning a lunatic asylum conducted by monks were brought to light last week in the course of a trial at the assizes at Aix-la-Chapelle (Rhenish Prussia). The case has produced a great sensation throughout Germany, and will no doubt be of particular interest to English readers, as the principal victim is an English Roman Catholic priest. The order of the Alexian monks, to whom is entrusted the care of insane persons and epileptics, possesses several lunatic asylums, both in Germany and elsewhere, under special ecclesiastical management. Public attention was drawn to these institutions by a pamphlet which was some months ago published at Iserlohn (Westphalia), bearing the sensational title "The Sufferings of the Reverend Mr. Forbes, of Scotland, at the Asylum of Marienberg." The author of this pamphlet, Herr Mellage, asserted that a veritable conspiracy existed between the brotherhood and certain bishops to confine as lunatics such priests as had fallen into disfavour with their superiors. He had obtained this communication from a chaplain who had succeeded in escaping from the asylum, and who had further told him that a Scotch priest, the Reverend Mr. Forbes, was still confined in the Marienberg Asylum, and had been treated there as a lunatic for three years. Moreover, among other things, he was assured that the patients were very badly treated. On Herr Mellage's representations a medical commission of inquiry was sent to the asylum, which, after only a minute's examination, declared Mr. Forbes to be sane, and ordered his immediate release. On the issue of the pamphlet the Superiors of the Brotherhood prosecuted its author for libel; but at the trial, which lasted from May 30th till June 8th, he succeeded in proving the truth of all his assertions. Mr. Forbes, who appeared in court, gave evidence that his bishop had asked him to go to Marienberg to be treated for a gastric disorder. He went under the impression that it was a Roman Catholic hospital, and not by any means a lunatic asylum. At first he was allowed outside the asylum, but the brothers, after accusing him of drunkenness, confined him definitively. The certificate required by law was easily obtained of the district officer of health. This certificate was based on a very short examination, which was, moreover, difficult, as Mr. Forbes could not speak German, and merely on the reports of the brothers and on a letter of the Bishop of Aberdeen, who, it was alleged, had stated that there was insanity in Mr. Forbes's family. In order to prove that the statement was unfounded the defendant's counsel had summoned witnesses from Inverness, Mr. Forbes's birthplace. It was,

indeed, an unwonted sight, that of half-a-dozen genuine Highlanders in a German law court. They all affirmed that to the best of their knowledge the members of Mr. Forbes's family had always been sane, admitting only that he was known as being somewhat eccentric, and that he had sometimes declared against the Pope and the Roman Catholic faith. Some medical men, who were called as experts, declared that Mr. Forbes appeared to be of a somewhat weak mind, but that he was not insane, that therefore confinement was unnecessary, and that a grave wrong had, according to their opinion, been committed against him. Still greater indignation was produced in court when it was stated by numerous witnesses that veritable medieval tortures were inflicted on the unfortunate victims in the asylum. It was a common thing to tie the arms and legs of those of them who protested and to dip their heads in cold water until they were nearly suffocated. In one case an inmate was placed on a hot stove till his back was scorched. Some of the victims are said to have died from blows on the head. The medical attendance amounted to a farce; although the asylum had nearly 700 inmates there was no resident physician. Two medical men had been appointed by the brotherhood, who alternately called for an hour daily at the office of the asylum and there inspected those of the patients who were brought before them by the brothers. They hardly ever entered the wards, and when cross-examined by defendant's counsel admitted that they had no special knowledge of mental diseases. They had no influence whatever, and the monks regarded them as their subordinates. As the result of the trial the defendant was, of course, entirely acquitted of the charge of libel, as all his assertions had been proved to be correct. When, after the verdict, the monks left the court they were hissed by the crowd assembled outside, and had to be protected by the police. They will now be charged with ill-treatment and with illegal incarceration, crimes punishable, according to German law, with three years' hard labour. They will, moreover, no longer be allowed to conduct asylums. Public opinion is justified in asking how such things could have been possible at the end of the nineteenth century in a city like Aix-la-Chapelle, and in a civilised country, to boot. No doubt the medical inspection by the district officer of health was wanting in thoroughness. It is impossible to understand how this official, whose duty it is to pay frequent visits to asylums for the insane—without, of course, giving previous notice—had been unaware of the terrible state of things existing in the Marienberg institution. He was also very indiscreet in giving a certificate of insanity in the case of Mr. Forbes. The behaviour of the two medical attendants attached to the asylum is still more blameworthy. They had neglected their duties, and in acquiescing in such proceedings had shown an indifference incompatible with the honour of medical men. Moreover, they had greatly prejudiced their own country by inducing foreigners to believe that it would be the easiest thing in the world to have an inconvenient person stowed away in a German asylum. Some time ago it was claimed at an ecclesiastical meeting that the treatment of the insane ought in most instances to be withdrawn from medical men and committed to the clergy. The Mellage trial will perhaps now make it appear that it is not at all advisable to increase ecclesiastical influence in the management of lunatic asylums, and that religion has nothing whatever to do with the treatment of mental diseases.

The Social Condition of Midwives.

In the last number of the *Archiv für Gynäkologie* Professor Fritsch gives his views on the present condition of midwives, and suggests some measures of reform. According to him it is very much to be regretted that the older midwives have had no training in antiseptics and are not sufficiently intelligent to understand its importance. Although in many districts post-graduate lectures instituted by the Government are delivered for the benefit of midwives, a great many midwives cannot attend the lectures on account of want of time or for other reasons. As they are obliged to abstain from attendance for a considerable time in cases of puerperal fever arising in any of their patients, they often endeavour to conceal the fact from their medical officers. In order to remedy this and other grievances some well-known obstetric surgeons established midwives' associations in order to give midwives an opportunity to complete their education, and to

relieve them if they were prevented from practising for hygienic or other reasons. A journal was also founded to support their interests, and to keep them acquainted with scientific progress. But these arrangements did not meet with much success; the midwives, for instance, of the smaller country places, where improvement was most called for, could not join the associations. In some places the associations, which were at first under the presidency of obstetric surgeons, very soon tried to get rid of their medical chairmen and assumed a rather hostile attitude towards the medical profession in general. They claimed to be no longer called "midwives" (*Hebammen*), but "lady obstetricians" (*Geburtshelferinnen*), and to be treated on the same footing as medical men. To avoid these bickerings Professor Fritsch suggests that midwifery should not be entrusted to women of the lower and uneducated classes, but that those of a higher social level ought to take up its duties. For that purpose the training of midwives ought to be modified. At present it is undertaken in what may be called seminaries, maintained by the provincial authorities, where the candidates have to board together for half a year. As this is not calculated to attract ladies of education, Professor Fritsch proposes that they should be trained in the lying-in hospitals attached to the universities, in common with the medical students. Of course special lectures would be delivered for their benefit. It would likewise be a great advantage to medical students if they learned the nature of the duties of a midwife. At present a young medical man may begin practice without having had an opportunity of observing midwifery, and thus is often at a loss what to do in the presence of a midwife. If the measures suggested by Professor Fritsch were adopted, and if ladies of good family agreed to undertake the arduous duties of a midwife, the social status of midwives in general would undoubtedly be greatly improved.

June 10th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Italian Red Cross.

I HAVE before me the official report of the Central Committee of the Italian Red Cross for 1894, a document full of interest, not only to Italians, but to all nationalities concerned in the humanitarian movement to which it belongs. To begin with, the financial condition of the committee is eminently satisfactory, its available funds amounting to 5 699,221 lire and showing an excess of 41,631 lire over the preceding year. Another most gratifying feature is the development of "mobilisable" hospitals for mountain and river service. One of the former I have already described as consisting of fifty beds and as having reached its Abyssinian destination under the direction of Dr. Gino del Prete; the latter has more than once been referred to in these columns as a new and ingenious departure in Red Cross organisation. To utilise the great waterways of the Alta Italia—so rich in lakes, in rivers, and in canals—for floating ambulances is a project to which Italy has taken very kindly, her many rowing clubs having contributed largely to the manning and the *matériel* of these Red Cross cruisers, of which working models have been on view between Lake Como and Milan, and the first of them was described in THE LANCET of Sept. 19th, 1891, under the title of the "Red Cross Afloat." Another highly instructive section of the report is that relating to the exercises and manoeuvres of 1894, when the Commander-in-Chief of the Army put on record his admiration of the promptitude and efficiency with which the ambulance service in all its departments was conducted. The diffusion of Red Cross hospitals over the provinces—the so-called "*ospedali territoriali*"—occupies another interesting page of the report, the success of the movement in the first five "*circoscrizioni*" being due to the energy and liberality with which the subcommittees coöperated in harmony with the academic authorities and private individuals. Moreover, the recruiting of the *personnel* of the association generally has marked a notable advance within the last official year, in the directing department 76 having been admitted and in the subaltern departments 248. These volunteer bands are all of certified efficiency, thanks in great measure to the courses of instruction given gratuitously by such clinicians as Professor Postemski, who fills the chair of Surgery in our university, and whose "*corsi d'istruzione*," four in number, were opened

to aspirants to Red Cross distinction in the beginning of the present year. Further sections of the report announce a new series of combined "*esercitazioni*" for 1895, and dwell with satisfaction on the intervention of the Italian Red Cross at the *Esposizione d'Igiene delle Facoltà Nazionali di Scienze Mediche* to be held at Buenos Ayres, and also on the fact that the association rendered heroic and efficient service during the recent earthquakes in Calabria—a service on which the Minister of the Interior congratulated the Comitato Centrale. Even in the Chino Japanese War the Italian Red Cross (as we learn from the report) was prepared to volunteer assistance to the Japanese conqueror, and only desisted on ascertaining that it had already been anticipated in the humanitarian offer by the Red Cross of Germany. Among the other features of the report is the gratifying assurance that the War Office has undertaken the expense of transporting all the *matériel* of the Red Cross at home and abroad, while a series of obituary notices of distinguished members of the association deceased within the last official year appropriately occupy the concluding pages.

The Ospedale Maggiore at Milan.

This great historical institution has just made a notable addition to its resources in a new pavilion for the treatment of surgical diseases. It is the gift of the Duchessa Litta-Bolognini in memory of her son Alfonso, and accommodates 120 beds. Every improved hygienic detail has been attended to by its designer and constructor, the engineer Emilio Sperioli, and at its formal opening on the 5th inst. a large company of the leading surgeons and practitioners of the city and province had occasion to admire its advantages in point of salubrious and cheerful exposure, of lighting and of ventilation, as also its many conveniences for clinical treatment and instruction. The building is hailed as a notable illustration of what Italy may yet do for her great hospitals by the further development of that pavilion system so much demanded in clinical schools still mediæval in character and still fraught with the manifold mischiefs summed up by the late Sir J. Y. Simpson in the word "hospitalism."

June 8th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Bay View Asylum Commission's Report.

IN October last a commission was appointed to inquire into the management of the Bay View Asylum, Sydney, and it has just presented its final report. It will be remembered that certain definite charges were made against Dr. Vause, the proprietor of the asylum, to the effect that a certain patient was unnecessarily placed in an isolated room without members of his family or the family physician being informed; (2) that he was confined in a stable which was cold, damp, and deficient in light and ventilation; (3) that the patient had no bedding and insufficient clothing; (4) that the room was not properly cleaned; and (5) that the patient was left for more than twelve hours without food or drink, and unattended. The commission deals with these charges *seriatim*. With regard to the first, they find that Dr. Vause carried out a practice which is in accordance with the rules for the management of similar institutions in Great Britain, America, and the colony, but that he committed an error of judgment in not giving information to the family. It is clear that in isolating the patient Dr. Vause was influenced solely by medical considerations, and not by motives of economy or convenience. As to the second charge, the commissioners find that although the building presents an unprepossessing appearance it was originally constructed for the purpose to which it was applied, and had been so used for many years with the approval of the Inspector-General of the Insane and the official visitors. They do not consider the rooms damp or ill ventilated, but think the ventilation might be improved. Regret is expressed that the rooms are detached from the main building and away from the rooms of the attendants. The allegations under Charge 3 are not regarded as of any consequence. The evidence shows that the patient was most destructive, and is conflicting as to the actual provision made; but the commissioners do not consider that purposes of economy entered into the arrangements. As to Charge 4, in the opinion of the com-

missioners the weight of evidence shows that the rooms were properly cleaned. The evidence on Charge 5 shows that the patient was amply provided with food and drink, and while there was some laxity in the matter of attendance he was not left over twelve hours unattended. The commission recommends that inspection of lunatic asylums should be more frequent. Dr. Manning, inspector-general of the insane, dissents from the general report on the general question of what ought to be understood by the term "seclusion" in regard to the insane.

*Dispute between the Surgeon and Captain of
H.M.S. "Ringarooma."*

A court-martial was recently held in Sydney to investigate a charge of wilful disobedience and contemptuous behaviour preferred against the surgeon of H.M.S. *Ringarooma* by the captain. Some dispute arose about the fixing of an operating table, and the captain became so excited that the surgeon considered he was mentally affected and unfit to command the vessel, which was to proceed to sea next day; he therefore ordered him on the sick list. The captain refused to go and placed the surgeon under arrest. At the court-martial a statement was made on behalf of the surgeon to the effect that the captain had appeared morbid and eccentric for some time past, and instances of eccentricity were detailed. The court refused to allow evidence to be called on the question of the captain's health, and after a short consultation found the surgeon guilty and ordered that he be dismissed from Her Majesty's service. Great indignation is felt at the verdict and at the mode of conducting the inquiry, and an effort will be made to challenge the decision.

Outbreak of Typhoid Fever at Erskineville, New South Wales.

Dr. Ashburton Thompson has presented a report on a recent outbreak of typhoid fever at Erskineville, New South Wales. Nineteen out of twenty-six infected houses were in one ward, and the associated conditions peculiar to that ward were the presence of cesspits and serious faults of subsoil drainage and house construction. The surface channels for foul water were improperly constructed, so that their contents soaked into the soil. The houses were often damp, and many were built on made ground with no impervious covering over it.

Management of Grenfell Hospital.

Dr. Ashburton Thompson has also presented a report on the management of the Grenfell Hospital. In September, 1894, charges of cruelty and neglect were preferred against the matron and medical officer in respect to a certain patient, and on his death the medical officer refused a certificate in order that an inquest might be held and the charges investigated. The coroner's jury found that the patient died from tuberculosis, and that "he was subjected to harsh and cruel treatment at the hands of the matron, and to negligence on the part of the medical officer." The matron and medical officer then resigned, but the latter was subsequently re-elected by the subscribers. Dr. Thompson is of opinion: "(a) That the medical officer failed to take up that independent attitude of caution and control which he should have occupied in the internal management of the hospital, and consequently fell justly under censure of the jury, although no important evidence was before that body to warrant it; (b) that the committee in general must share that same censure in that their supervision and management were such as did not secure to the sick such skilled nursing, humane attention, and necessary appliances (at the least) as are properly believed by the public to be usually provided in a hospital." He recommends further that no person should be appointed matron or nurse in a hospital subsidised from public funds who has not been trained as a nurse, and that the medical officer to the Government should be supplied with proof of adequate training of the person selected before approval is given by him to the appointment.

The Financial Condition of the Melbourne Hospital.

The finances of the Melbourne Hospital are far from satisfactory. The total indebtedness amounts to about £14,000, caused by a reduction in the Government subsidy, payment of heavy interest, and falling off in subscriptions. The committee have reduced expenditure and retrenched in every possible way, but the debt remains. A largely attended public meeting was held in the town hall on April 24th, and it was decided to make a special appeal on behalf of the hospital funds to all classes of the community by a week of self-denial. Circulars will be addressed to the mayors of all the suburban municipalities and of the principal cities

and towns, inviting them to constitute themselves collecting centres; and cards will be issued to be distributed to every individual household, explaining the objects of the movement and inviting the coöperation of every member in the house, and it is hoped sufficient funds will be raised by this means to wipe off the debt.

Aneurysmal Varix of the Left Innominate Vein.

At the March meeting of the South Australian Branch of the British Medical Association Dr. J. C. Verco showed a boy aged twelve with a condition diagnosed as aneurysmal varix of the left innominate vein. There was a distinct thrill on the left side of the neck beneath the sterno-mastoid, continuous with slight systolic increase. On auscultation a very low humming murmur was heard, with its seat of maximum intensity over the left clavicle, about one inch and a half from its inner end, and traceable obliquely downwards and inwards across the sternum from the left first interspace to the right second cartilage, with gradually diminishing intensity. It was continuous with a distinct systolic increase, and was more marked in the recumbent than in the erect posture. The normal heart sounds could be heard distinct and pure, and the murmur could be traced from the clavicle upwards into the neck and outwards along the line of the left subclavian and axillary veins to a point below the insertion of the pectoralis major. The boy had suffered from fits since he was eighteen months old. He had had no other illness except measles. Dr. Verco concluded there was a communication, probably congenital, between the left innominate vein and either the arch of the aorta or, more probably, the left carotid artery.

*Ligature of Carotid and Subclavian for Innominate
Aneurysm.*

At the Melbourne Hospital recently Mr. Charles Ryan successfully tied, first, the right carotid artery, and then a week later the right subclavian for a large innominate aneurysm. The patient has done very well so far, and the aneurysm appears to be consolidating.

Bullet Wound of Femoral Artery.

Mr. Ryan also operated recently on a very interesting case. A boy was shot in the thigh with a revolver, and also in the mouth. There was very little extravasation of blood in the thigh, but no pulsation could be felt in the tibial arteries, and it was decided to cut down on the femoral. It was found that the bullet, which was smaller than the calibre of the vessel, had passed exactly through the centre of the artery. It was ligatured above and below, and the wounded portion excised. The inner coat had retracted and the vessel above and below the wound was plugged with clot; hardly any hæmorrhage had taken place.

Leprosy in Queensland.

At the last meeting of the Medical Society of Queensland Dr. Hardie exhibited a boy eleven years of age, of English descent but born at sea, suffering from leprosy. So far as is known he had never come in contact with any cases of leprosy and had been attending school. The diagnosis was confirmed by bacteriological examination, and filarise were also found in his blood.

Renal Surgery.

At the last meeting of the Victorian Branch of the British Medical Association Mr. G. A. Syme read some Further Notes on Renal Surgery, and brought forward two cases of nephrectomy and one of floating kidney associated with perinephritic abscess. The interest of the first case of nephrectomy was that it was performed for carcinoma occurring in a kidney from which a large calculus had been previously removed by nephro-lithotomy.

Appointments.

Mr. Fred. D. Bird, M.B., M.S. Melb., M.R.C.S. Eng., has been elected Lecturer on Surgery in the University of Melbourne; Mr. G. Rothwell Adam, M.B. Edin., has been appointed Medical Officer to the Infirmary Department of the Women's Hospital, Melbourne, as locum-tenent for Dr. Rowan, absent on leave; Mr. A. E. Salter, M.B. Melb., has been appointed Resident Medical Officer to the Midwifery Department of the Women's Hospital, Melbourne; the Hon. Dr. MacLaurin has been elected Vice-Chancellor of the Sydney University; Mr. E. H. Binney, M.B. Syd., has been elected Senior Resident Medical Officer, and Messrs. R. R. McKinnon, M.B. Syd., M. Veech, M.B. Syd., G. F. Rutter, B.A., B.Sc., M.B. Syd., and E. J. Spark, M.B. Syd., have been elected Resident Medical Officers at the Sydney Hospital.

Obituary.

ALFRED SWANN, M.D. BRUX., M.R.C.S.

WE regret to have to announce the death of a valued contributor to our columns in the person of Dr. Alfred Swann, the medical officer of health for Batley. On May 31st he attended at the House of Lords to give evidence in connexion with the Don water scheme, and upon his return home expressed himself as feeling ill. On June 4th paralysis supervened, and he lapsed into unconsciousness, from which he never recovered. He expired on Thursday, June 6th, the cause of death being cerebral hæmorrhage. Dr. Swann at the time of his death was forty-four years of age. He received his early education at Rawdon Friends' School, after which he studied medicine in Birmingham and at University College, London. He settled at Batley in 1880, and at once began to interest himself in sanitary questions. The health of the town was at that time in a very low state, and the main cause of this was traced by Dr. Swann to the town water-supply being largely contaminated with lead. In 1884 he was appointed medical officer of health, and so was enabled to carry out reforms which he had long foreseen were necessary, though, like all reformers, he was hindered by those who considered, rightly or wrongly, that their interests were being attacked. He held many other appointments, such as certifying factory surgeon, surgeon to the police and Volunteer forces, as well as to the Great Northern Railway Company. He was a true friend to his patients, and ever ready to contribute with his purse as well as with his knowledge to the welfare of the poorer class who sought his advice. He contributed many interesting and valuable papers to our columns, notably communications on Lead Poisoning and various ophthalmic and surgical subjects.

JOSEPH MILLS, M.R.C.S. ENG.

ALL old St. Bartholomew's men, and many of the profession not connected with that hospital, will hear with regret of the death of Mr. Joseph Mills, formerly anaesthetist to the hospital. For some time past he had been in failing health, and a pathetic circumstance connected with his death (which occurred on May 29th at Andover) was that the day before, his wife, who had nursed him devotedly and never left him for eighteen months, came up to town for the day, "because he was so much better." He was the son of the late Robert Mills of Inkpen, and was educated at Andover and Weymouth. He commenced his medical studies at Winchester as a pupil of Dr. Richards, and afterwards entered at St. Bartholomew's, where he became house surgeon to the late Sir William Savory. He was appointed anaesthetist in 1875 and resigned in 1893. His health failed somewhat in 1886-87, but not until 1888 was any serious mischief discovered. It was then found that he had apical trouble, with some pleuritic effusion. He rapidly improved under treatment and spent the winter at Davos. On his return to England in April, 1899, he was in excellent health, and in spite of an attack of influenza in 1890, he continued in good health until the end of 1892, when he began to suffer from cough. In the spring of 1893 he gave up work and retired to Andover. During the last two years he led the life of an invalid, but he was always bright and cheerful, and was much delighted to see any of his old friends. He died quite suddenly on May 29th from pulmonary hæmorrhage. He leaves a widow and one daughter. Of his unvarying kindness and courtesy as a teacher the writer of this brief and imperfect notice can speak from personal knowledge, and though for some years he had retired from active work his memory is green in the hearts of all who knew him.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon [the 10th inst.], Sir James Crichton-Browne presiding. The following were elected members: Mr. Benjamin Bennett, Mrs. Henry Burton Buckley, and Mr. William Watson Cheyne, F.R.S. The special thanks of the members were returned to the Right Hon. Lord Playfair for his donation to the fund for the Promotion of Experimental Research at Low Temperatures.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

OUR report of the session of the Council published in last week's issue carried the proceedings to the close of Wednesday, June 5th—that is to say, the eighth day of the session. The Council met again on Thursday, June 6th, when, greatly to the relief of the members it succeeded in getting to the end of its work.

The New Edition of the Pharmacopœia.

THE PRESIDENT presented the report of the Pharmacopœia Committee. It stated that applications for information bearing on the production of the new edition of the British Pharmacopœia had been sent to twenty medical authorities, and that from sixteen of these communications of great value had been received. The Therapeutic Committee of the British Medical Association had sent in a memorandum furnishing important information as to the frequency with which a considerable number of official drugs and preparations are used by the members of that association. The Pharmaceutical Society had supplied the committee with an instructive report and statistics, and Mr. Martindale had forwarded a pamphlet in which the number of times certain drugs and preparations appear in 12,000 prescriptions was stated. Many communications had also been received from the colonies and India which had been summarised by Professor Attfield. Dr. Tirard had consented to act as secretary to the Pharmacopœia Committee. The committee propose to invite Mr. Thisleton Dyer, C.M.G., F.R.S., and Mr. Holmes to act as referees in botany, and to ask Dr. Thorpe, F.R.S., to act as referee in chemistry, or Dr. Russell, F.R.S., if Dr. Thorpe be unable to accept the invitation of the committee. The Pharmaceutical Society of Great Britain have, at the request of the General Medical Council, appointed a committee of pharmacists to assist the Pharmacopœia Committee in the work of revision. In pharmacology and therapeutics Dr. Lauder Brunton, Professor Fraser, and Professor Walter Smith will be requested to act as referees. The Pharmacopœia Committee have already held three meetings during the present session of the Council, and, in order to deal adequately with the materials before them, and to consider the preparation of the first draft of the new Pharmacopœia, the committee propose to hold a meeting in London towards the end of July.

Dr. HERON WATSON asked whether the communications furnished by the various authorities mentioned in the report would be presented to the Council.

THE PRESIDENT replied that the communications were of a very satisfactory kind, and should be sent to all the bodies, as well as to members of the Council.

Dr. HERON WATSON recalled to the Council the remit with reference to the £1250 to be paid to Professor Attfield, and asked why there was no reference to the matter in the report of the committee.

THE PRESIDENT replied that nothing more had been done with regard to Professor Attfield's salary. Professor Attfield had been hard at work, and it was to him they owed the summaries and condensations of the papers.

Dr. HERON WATSON said he did not doubt that, but he was speaking with regard to the remit and the payment of the £1250.

THE PRESIDENT assured Dr. Watson that Professor Attfield would not accept less, and the Committee had appointed him to do the work. He also appealed to the Council to have confidence in the Pharmacopœia Committee.

Dr. HERON WATSON said he did not want to express the smallest want of confidence either in the President, to whom they owed so much, or any member of the committee, or in Professor Attfield, who he believed was the backbone of a great deal of work that could not very well be done by anybody else. All he spoke to was a question of order.

Dr. LEECH moved the adoption of the report, and in doing so referred to some of the work being done by the committee.

The motion, after being seconded by Mr. BRUSHFIELD CARTER, was adopted.

The Conjoint Professional Examinations of the Royal College of Surgeons in Ireland and the Apothecaries' Hall of Dublin.

Sir DYCE DUCKWORTH, chairman of the Examination Committee, said it was now the duty of the Council to consider one of the most important questions that had ever come before it. It affected the future of one of the medical corporations in the three kingdoms, indeed, he might say its very existence was at stake. It was the first occasion on which any business of the kind had been before the Council since the passing of the Medical Act of 1886. He would explain briefly the state of the case. This Conjoint Board of the Royal College of Surgeons in Ireland and the Apothecaries' Hall of Dublin had now been inspected no less than four times. The Final Examinations were examined twice by the inspector of the Council, together with one of the members of the Council, Mr. Bryant, and on two occasions by command of the Council the whole of the professional examinations of the board were examined by the inspector of the Council together with another member of the Council, Mr. Wheelhouse. The last examination took place in April, and the report had only been out a short time; but the whole matter was now in order, because they had an official letter saying that the Conjoint Board had no reply to make to the observations of the visitor and inspector. As the matter was important he hoped the Council would allow him to read a portion of the report of Mr. Wheelhouse and Dr. Duffey on the professional examinations held by the Conjoint Board in April and May of the present year. With regard to the First Professional Examination, the visitor and inspector said it was a good and satisfactory test. As to the second, they said that the solitary candidate at the examination presented himself for his second re-examination after a lapse of nearly six years since his first re-examination in two subjects of it only—viz., anatomy and materia medica and pharmacy—and, as on the two former occasions on which this examination was reported upon, the examination in both these subjects was commendable. As to the Third Professional Examination, they said that no exception could be taken to any part of it. As to the Final Examination, they had pleasure in reporting an improvement generally in this examination. The only remark that it appeared necessary to make as regarded the examination in surgery, which on the whole was as satisfactory as heretofore, was that at the oral examination no "specimens, wet or dry, casts, models, &c." were used by the examiners, as the regulations laid down for them recommend. At the oral examination in midwifery and gynaecology there were no morbid specimens provided for examination. A similar omission had been noted in the three last reports. The standard of the examination in medical jurisprudence and in hygiene was higher than that at the three previous visitations. The examination in pathology was quite satisfactory, but they question the advisableness of making a practical examination in urine-testing a part of it. Then the visitor and inspector gave the following conclusion—viz.: "We report that the First, Second, and Third Professional Examinations of this Conjoint Board are 'sufficient.' The Final Examination has been improved in many ways. The examination in medicine was a most careful one, and, we believe, was conscientiously conducted. Holding this opinion honestly, and feeling with the examiners that the candidate they examined had a good theoretical knowledge of medicine, we greatly regret we cannot agree with their judgment in passing him on his clinical examination. In it he showed (1) that he could not ascertain with any degree of accuracy the conditions that presented themselves in a well-marked case of unilateral pleural effusion; that (2) he was unable to recognise the presence of albumen in large quantities in a specimen of urine; and (3) that he could not examine urine for sugar. This proved, in our opinion, that the candidate did not possess 'the requisite knowledge and skill for the efficient practice of his profession' (Medical Act, 1858, Sec. xx.). Excellence in the written or oral examination should not be allowed to compensate for failure in the clinical. For these reasons although we have no fault to find with the actual examination itself, the fact that a candidate was passed who exhibited gross ignorance of clinical medicine compels us to report that in medicine the examination was not 'sufficient.' In the other subjects we report that the Final Examination was 'sufficient.'" He would now read to the Council the report drawn up by the Examination Committee. It was to this effect: "The

Examination Committee, having discussed the report of the inspector and visitor on the fourth inspection of the entire professional examinations of the Conjoint Board of the Royal College of Surgeons in Ireland and the Apothecaries' Hall of Dublin, and having been officially informed by the representatives of these two bodies that they have no remarks to offer upon this inspection, finds that the examination is declared to be insufficient within the meaning of the Medical Act of 1886 in respect of the subject of medicine, although generally sufficient and in some respects excellent in surgery. The Examination Committee, therefore, has to report to the Council that no one of the four inspections of this conjoint examination has afforded proof of its sufficiency in all its statutory departments. The Examination Committee accordingly recommends the Council to represent the same to Her Majesty's most Honourable Privy Council." This was the conclusion of the Examination Committee. It would be in the remembrance of the Council that upon a former occasion as the result of two inspections the Examination Committee thought itself justified in recommending the Council to represent the state of matters to the Privy Council, but tenderer mercies prevailed, and it was thought that another inspection should be made and more time given to see if amendment was possible. Twelve months more had been allowed to this board. Two more examinations had been held and two more inspections had taken place. He begged to move: "That it appears to this Council that the standard of proficiency in the subject of medicine required from candidates at the qualifying examinations held by the Conjoint Board of the Royal College of Surgeons of Ireland and the Apothecaries' Hall of Dublin, after four special visitations, has been found insufficient."

Mr. BRYANT, seconding this, said that it fell to him to visit the Conjoint Board on two occasions. The decision he came to with the inspector on the first occasion was that the examinations in forensic medicine and in hygiene and in medicine could not be regarded as sufficient, and on the second occasion the decision was the same. After reading in the third and fourth reports that the same conclusion was reached he felt perfectly sure that they would be failing in their duty if they did not represent to the Privy Council this very serious state of things.

Mr. WHEELHOUSE said that as he had been engaged in the last two examinations of this Conjoint Board it behoved him to tell the Council his feeling in the matter. He could not but hope on the first occasion on which he visited the examination, judging by the report which had been made to the Council before, that there was a great effort being made to improve it, and he believed that the effort was to a very considerable extent successful. He believed that the third examination was a more perfect one than the first or second, and that at the last one further effort was made in the way of improvement. On reading the last report he thought they would see that they were tolerably well satisfied, except with regard to medicine, and in that connexion there was only one point with them. The question that arose in the mind of the inspector and himself was that a man who showed himself well versed so far as theory was concerned in his medical education, but who knew nothing whatever apparently of practice, should have been passed as a qualified man; and they came to the conclusion that it was a question whether he ought to have been passed or not.

Sir DYCE DUCKWORTH said he thought the Council should have before it the report of the Examination Committee on the report of the inspector and visitor with regard to the examinations in October, 1894. In this report the committee said:—

"The visitor and inspector send in a report on the First, Second, Third, and Final Examinations of this board as held in October, 1894, and express the opinion that the First, Second, and Third of these Examinations are good and satisfactory tests. The Final Examination generally has been much improved since the last report, but the Examinations in medicine, forensic medicine, and hygiene are not considered 'sufficient.' The oral examination in gynaecology was imperfect, and it is recommended that pathological specimens illustrating the diseases of women should in future be employed. New regulations have been made, but some of the examiners were not fully acquainted with them. The First Examination may be passed in piecemeal fashion. The examination in osteology may be passed at the end of the first winter session, but the questions are considered somewhat difficult for a student of anatomy who has had only one such session of study. The examiners in each subject set their own papers, but these are not, as they should be, subsequently submitted to the whole board. Only three out of six questions have to be answered. The Second Examination may also be passed in piecemeal fashion. The written examination for the second part revealed some amazing ignorance and unpreparedness on the part of the candidates, the like of which the visitor and inspector had never before met with. The same remarks apply to the oral examination in

hospital practice, anatomy, physiology, and materia medica. In practical physiology and histology the examination, while adequate as far as it went, was incomplete. The representatives of the Royal College of Surgeons on this Conjoint Board send in a separate report in reply to the report of the visitor and inspector, and state that no part of the examination conducted by the examiners appointed by them has been reported on as unsatisfactory. They hold aloof from their colleagues of the Apothecaries' Hall, and answer only such charges of irregularity as apply to the examiners of their College. This is a new departure, which the Examination Committee trusts may not be followed by any other Conjoint Board. It is alleged that the visitor's and inspector's reports are 'most unfair,' because they give details of bad answering on the part of unsuccessful candidates. But it appears that the liberal marking of unworthy candidates went very near allowing them to pass, and the Council requires a report upon the methods pursued in each examination which is inspected. The College of Surgeons' representatives further express regret that the visitor's and inspector's reports are not written in a more 'judicial' tone. The Examination Committee, however, would remind the General Medical Council that that body desires, and is accustomed to receive, reports, and not judicial utterances, from its visitors and inspector, and reserves to itself alone the power to pronounce 'judicially' upon such reports. Reviewing the whole evidence forthcoming from the several inspections of this board, the Examination Committee desires to express its opinion that, while recognising the efforts which have been made to comply with the recommendations of the General Medical Council by the Conjoint Board, the results are still unsatisfactory."

Sir PHILIP SMYLY, the representative of the Royal College of Surgeons in Ireland, then addressed the Council. He began by reading Section 3 of the third clause of the Medical Act of 1886, in which it stated that the General Medical Council shall forward a copy of their inspector's report to the Privy Council. This reporting to the Privy Council had been held in *terrorem* over them, and he desired to point out that all these reports should have been reported to the Privy Council.

Dr. MACALISTER said the report was only completed to-day, and the time had not come to report to the Privy Council.

Sir PHILIP SMYLY replied that he was referring to former reports. He wished to be clearly understood that he made no charges against the Apothecaries' Hall. The Apothecaries' Hall had always met their suggestions very favourably, and had adopted them in nearly every case. The examiner in medicine must be a hospital physician—that was to say, practically a Fellow of the Royal College of Physicians; and the defects in the examination were accounted for by the systematic boycott instituted by the Royal College of Physicians, which he left his colleague, Dr. Charles Moore, to explain.

Dr. ATTHILL, who represents the Royal College of Physicians of Ireland, said he thought "boycott" a most improper word to use.

Sir PHILIP SMYLY undertook to justify its use. There were three divisions of the word "boycott." One was the method that was adopted in Ireland of putting a bullet through a man; that, as the Kerry man said, precluded a man from holding land for the rest of his life. The second method was that of shooting him in the legs and making him so uncomfortable that he would not hold land. The third method was to starve him out and not allow him to trade or deal with anybody. The first method was performed by the Royal College of Physicians when it issued an injunction from the Court of Chancery prohibiting them from holding the conjoint examinations at all. That was analogous to shooting, but fortunately, as often happened in Ireland, they missed. The second method, of shooting in the legs, was paralleled by the charges which were brought against the Conjoint Board for irregularity. They tried to frighten the board out of their lives by all these charges. These also in a measure fell to the ground. As to the third method, the Royal College of Physicians had carried out a cruel system of starving. The report of the Examination Committee was hardly fair. If members looked through the reports furnished by the inspectors they would find that they obeyed the instructions of the Medical Act and used the two words "sufficient" and "insufficient." In last year's report the inference to be drawn from the advice given was that the Royal College of Surgeons should withdraw from the Conjoint Board. The words were: "The Examination Committee think it would be very desirable that the General Medical Council should suggest to the Royal College of Surgeons in Ireland the propriety of severing their connexion with a board whose proceedings can be thus described." The Royal College of Surgeons promptly acted upon this advice and gave the legal notice, and the Conjoint Board would cease to exist next month. Referring to Mr. Wheelhouse and Dr. Duffey's report, he said there was no word of censure upon the surgical side of the board, and he submitted that the portions of the examination conducted by the Royal College of Surgeons had not been such as to require this Council to report the

examination as a whole, and without any explanation or qualification, to the Privy Council, thereby inflicting an injury to the reputation and prestige of one of the oldest Royal Colleges of Surgeons in the empire. He submitted to the Council that the Royal College of Surgeons in Ireland came out of this matter with clean hands.

Dr. CHARLES MOORE, the representative of the Apothecaries' Hall, then addressed the Council. It was hardly fair, he said, to condemn a body for a particular branch, all-important though it might be, when they were deprived of the means of seeing to that particular branch. Repeated instances had come before him of gentlemen being asked to carry on the medical examination in Dublin and declining. The reason given either directly or indirectly was fear of the displeasure of the Royal College of Physicians. He was glad to say that it was not, properly speaking, the Royal College of Physicians who were at fault, but merely what was called the Young Ireland Section of the College, who were in a majority in a matter of this kind. He had to complain of some of the criticisms offered. He objected to the term "piecemeal," and he complained that the reports of the visitor and inspector were not written in a more judicial tone. Moreover, when the inspector undertook to cross-examine the examiner he thought he went altogether *ultra vires*. As to the position of the Apothecaries' Hall, he might say that its members, about 900 in number, were scattered throughout Great Britain and Ireland and the colonies, and were among the ablest and most esteemed members of the medical profession. Dr. Atthill had spoken about "the scum," but he thought the expression uncalled for and altogether inapplicable. As to the unfortunate student referred to in the report, he took it that he was frightened, for he had passed very successfully the written and theoretical examination.

Mr. WHEELHOUSE denied that Dr. Duffey interfered with the examination or the work of the examiner.

Mr. BRYANT offered a similar denial.

Dr. ATTHILL said that the remarks of Sir Philip Smyly and Dr. Charles Moore made it necessary for him to speak on an occasion when he had desired to remain silent. It was true that the Royal College of Physicians did not consider the Apothecaries' Hall a medical corporation in the proper sense of the word, and that they had tested the right of the Apothecaries' Hall to be so considered by taking proceedings in the Court of Chancery. The decision went against his College. Their counsel—very eminent men—told them without any hesitation that they ought to appeal, but so far from wanting to persecute or give unnecessary trouble they said if the bodies kept up a good standard of examination they would not proceed further in the matter. This Council a year ago took proceedings against the Royal College of Physicians of London for its giving a licence under its Charter. Was that boycotting the Royal College of Physicians of London? He was surprised at Sir Philip Smyly using such a simile. Then he charged the Royal College of Physicians of Ireland with boycotting them by bringing forward before this Council irregularities. These irregularities were accepted by the committee and accepted by the Council.

Dr. KIDD suggested that it was waste of time to proceed with this debate, having regard to the fact that the Conjoint Board ceased to exist on July 1st.

Sir DYCE DUCKWORTH thought the debate should proceed, his opinion being that it was most instructive and useful.

Dr. ATTHILL proceeded with his speech. He related to the Council certain information which had reached him with regard to what took place at examinations of the Conjoint Board, and asked whether it was for his College to remain quiet and allow a system to go on which was a disgrace to Ireland, a disgrace to Great Britain, and, above all, a disgrace to this Council. He had used the word "scum" accidentally, and he apologised for having used it to the extent of substituting "refuse." These men were the refuse of the medical schools of Great Britain and Ireland, and he stuck to his terms, no matter whether he gave offence or not. It was said that his College had prevented their Fellows from examining for the Conjoint Board, and, speaking with perfect knowledge of all that went on in the College, he absolutely denied this. In support of his denial Dr. Atthill read to the Council a number of letters from Fellows, one of whom had actually examined for the Conjoint Board. In conclusion, he denied that there had been anything like a boycott, or an attempt at such a thing.

Dr. CHARLES MOORE said he had a letter from a Fellow who declined to act because he feared the displeasure of his College.

Sir JOHN BANKS said that if the condemnation which had been pronounced upon this examination was complete he should not have one word to say in mitigation of the severe punishment which it was proposed to inflict upon the Conjoint Board. But it was not complete. He could not therefore vote for the proposal to go before the Privy Council.

Dr. HAUGHTON said that as a Fellow of the Royal College of Physicians of Ireland he would be very far from going so far as to use the term "boycott" to the College; but there was what he must call not a friendly feeling between the College and the Apothecaries' Hall. He, as a Fellow of the College, dissociated himself entirely from that unfriendly feeling.

The motion was then put to the Council and carried by 17 votes to 4.

Sir DYCE DUCKWORTH, seconded by Mr. BRYANT, moved: "That in accordance with Section IV. (1) of the Medical Act (1886), the General Council do now make a representation to that effect to the Privy Council."

Dr. KIDD moved an amendment the effect of which was that, as the Conjoint Board was now practically defunct, it was unnecessary to proceed to the Privy Council.

Sir PHILIP SMYLY seconded this amendment.

Dr. MACALISTER said he did not think the Council had any option in the matter, having once decided that the examination was insufficient.

Sir PHILIP SMYLY pointed out that last year a resolution not to inflict this penalty was carried.

Dr. MACALISTER agreed that the Council could choose its time, but the present proposal was that the Council should never make the representation.

Sir WILLIAM TURNER said that this point had been submitted to their legal adviser, Mr. Muir Mackenzie, whose advice was that they were not bound last year to make the representation to the Privy Council at that particular meeting. The Council came to the resolution to defer making the representation, and it ordered further inspection of the examination. There had been further inspection, and he for his part felt they were bound now to comply with the injunction in Section 4 of the Act.

It was agreed not to press the amendment, and on the motion of Sir Dyce Duckworth being put it was carried by 20 votes to 4.

Sir DYCE DUCKWORTH moved: "That, pending the consideration by the Privy Council of this representation, the General Council come to no decision on the application by the Apothecaries' Hall of Dublin, of Nov. 23rd, 1894, to appoint two Examiners in Surgery under the provisions of the Medical Act (1886)." He thought it would be agreed that in the circumstances it would be premature for them to exercise the privilege invested in the Council of appointing examiners as asked.

Mr. BRYANT seconded the motion.

Sir WALTER FOSTER said that Dr. Charles Moore, as representing the Apothecaries' Hall, was quite willing to allow this resolution to pass and not to press for the appointment of examiners this session. Pending the decision of the Privy Council, it might be unwise to come to any vote in this Council.

Sir WILLIAM TURNER asked if they were to understand that Dr. Charles Moore withdrew the letter of application. If he did withdraw it Sir Dyce Duckworth's resolution must drop.

Dr. CHARLES MOORE thought the most suitable course to adopt in the circumstances was to request leave to withdraw the letter of application pending decision of the Privy Council on the representation that was to be made to it.

Leave was given, and the subject dropped.

The letter in question was from the Secretary of the Apothecaries' Hall of Ireland, and stated that the Governor and Court of Directors of the Hall at a meeting on Nov. 23rd, 1894, "resolved to petition the General Medical Council to appoint two examiners in surgery under the provision of the Medical Act, 1886, as their conjunction with the Royal College of Surgeons will cease in July, 1895. When permission is granted the court will be prepared to submit two names for approval of the Council, or receive two names from the Council if so directed."

Report on Qualifying Examinations.

Sir DYCE DUCKWORTH, as chairman of the Examination Committee, said that as the cycle of three years' inspection had now been completed, the Examination Committee had considered their "Report on the Visitation and Inspection of the Final Qualifying Examinations of the Universities and

Licensing Bodies of the United Kingdom." That committee represented that:—

"The whole of the Final Examinations of the several universities and licensing boards in the three kingdoms having now been visited and inspected, the Examination Committee begs leave to offer the following report upon them as a whole. The committee is pleased to find that these examinations are, with one exception, deemed to be 'sufficient' within the meaning of the Medical Act of 1886. In most instances the criticisms of the visitors and inspector have been kindly received, and many defects pointed out have already been acknowledged and rectified. While taking note of the general sufficiency of these examinations, the committee must state that the standard, as might be expected, is found to vary in different institutions. We can never expect absolute uniformity to prevail amongst bodies so widely different in character as are the seventeen universities and conjoint boards of the medical corporations in the three kingdoms. We look for distinctly higher standards in the cases of all the universities granting degrees in medicine, surgery, and obstetrics, but even among them it is not possible to institute exact comparisons. The profession no less than the public is now, with one exception, adequately protected against the admission of imperfectly trained practitioners into the ranks of medicine, and it is also distinctly true that the standard of qualification has been materially raised in every licensing body within the last twenty years. The Examination Committee finds evidence of imperfect early education on the part of many candidates who ultimately become members of the profession, and strongly urges that more strenuous efforts than have hitherto been attempted may be made to secure a higher standard of general education before registration as a medical student is permitted. The Examination Committee takes note of a frequently repeated criticism as to the advisability of requiring, in addition to the ordinary examination of cases, a written report on at least one medical and surgical case in the clinical portion of the examinations. The committee recommends this test to be employed when it can be efficiently carried out. The number of cases of midwifery on which attendance is required is in some instances too few, so small a number as six being considered adequate by some boards. In reply to unfavourable comment upon this matter, these boards declare that it is impossible to provide for a larger number being attended. It is manifestly not easy to find a remedy for this condition, but the Examination Committee is unwilling to believe that the difficulty is insuperable. If the local provision for midwifery instruction in the educational centre itself is inadequate the necessary knowledge could surely be secured elsewhere, under the competent supervision of a registered practitioner, or in a lying-in institution, and certificates be produced of attendance on a large number of cases. The Examination Committee suggests that the Council should consider the propriety of issuing a recommendation to this effect. A more frequently reiterated complaint is made by the visitors and inspector respecting the failure to institute any dependable test in operative surgery. Some boards declare their inability to carry out this test by reason of insufficient supply of material for the purpose. It is manifestly unwise to urge this examination on licensing bodies which are willing, but which, on account of the restrictions imposed by the Anatomy Act, are absolutely unable to conduct it, and the Examination Committee is of opinion that the Council cannot for the present proceed further in pressing this matter upon the attention of the bodies concerned. It is pointed out by the inspector that many of the examining boards hold no special examination in ophthalmic or in aural surgery or in skin diseases. In other cases it appears that candidates are thus tested in the course of the several surgical examinations. The General Medical Council has hitherto made no recommendation respecting special examinations in these subjects. The Examination Committee sees a difficulty in urging the Council to make more specific recommendations on these points, since such a course might lead to the introduction of other tests in special subjects to a burdensome degree. The curriculum of study is now so loaded and the requirements in examinations so detailed and onerous, that it appears advisable to exact nothing further at the present juncture. It might suffice to indicate to the several boards that the Council expects the subject of ophthalmology to form part of the examination for a qualifying licence to practise, and that candidates should be also examined, as far as practicable, in their knowledge of skin diseases. The Examination Committee, by way of summary, would ask the Council to emphasise the desirability of all the examining bodies observing the following points:—

- "1. The maintenance of fixed intervals of time between the several examinations. It is desirable that two years at least should intervene between the examination in anatomy and physiology and the final examination in medicine, surgery, and midwifery.
- "2. The error of sanctioning the extreme subdivision of examinations, and particularly the final, as now permitted by the English, Scottish, and Irish Conjoint Boards.
- "3. Questions in all the written examinations of the different bodies should be submitted to the whole of the examiners under each subject before they can be set at any examination.
- "4. The careful supervision of the candidates in all their examination work.
- "5. The justice of allowing at least half an hour for a candidate to answer each question in the papers on medicine, surgery, and midwifery.
- "6. The rule that no candidate should be examined in any subject or part of a subject, except in the presence of two examiners.
- "7. The necessity of the clinical examinations in medicine and surgery being conducted under the personal surveillance of an examiner, who should always examine the candidate orally on each case, although the adoption of this rule might in practice necessitate in some boards additional clinical examiners.
- "8. That there should always be an examination in the testing of urine and other secretions, in microscopy, and in prescription-writing, and always an oral examination in both medicine and surgery, which should include the recognition of pathological specimens.
- "9. That at every final examination there should be a practical examination in pathology, macroscopic and microscopic, unless this has been included in the examination immediately preceding the final examination.
- "10. The examination in midwifery, forensic medicine, and hygiene should be made as practical as possible.
- "11. Whatever the system of marking may be, the percentage for a pass (50 per cent.) should be uniform in all the boards and in accordance with the recommendations of the Council. The marks given on the

written examination ought not, as is the case with some boards, to dominate those given at the oral and clinical examinations. The recommendation of the Council that knowledge of one subject should not be allowed to compensate for ignorance in others is not sufficiently regarded by some of the examining bodies. Marks given in any part of an examination should be given on the merits of that part alone, and not be subject to future revision unless for the correction of a manifest error.

"12. That as the art of examining is only to be acquired by practice, it is desirable that an examiner should be re-elected where practicable for at least five consecutive years, particularly for the Final Examination."

These, said Sir Dyce Duckworth, were the results that came out from the inspection of the Examining Boards of the three kingdoms, and he proceeded to read an appendix to the report, which appeared to show that among the candidates who have presented themselves to the several Examining Boards there have been some whose ignorance has been such as to render it incredible that they should ever become competent and trustworthy medical practitioners. The committee thinks it highly desirable that such persons should be altogether excluded from the ranks of the medical profession, and recommends the Council to seek the coöperation of the several licensing authorities for this purpose. He moved that the report be received and entered on the minutes.

This was seconded by Mr. WHEELHOUSE and agreed to.

Dr. BATTY TUKE asked if it was contemplated that this report was to be considered during the current session.

Dr. MACALISTER thought the committee's conclusions were very important, and he suggested that they should be drawn up in the form of "recommendations" by the Council for consideration next session.

The PRESIDENT: The bodies should have an opportunity of sending any representations in regard to them. Do you propose to send them to the bodies?

Sir WILLIAM TURNER and others: No, no.

Dr. MACALISTER: They deserve to be permanent recommendations.

Sir WILLIAM TURNER: But they cannot now be sent to the bodies, because the Council may alter them.

Dr. MACALISTER: Then I move "That the Examination Committee be instructed to prepare for the consideration of the Council at its next session, in November, a series of specific recommendations embodying the results set forth in the summary to their report."

Dr. McVAIL seconded this proposal.

Dr. PETTIGREW: I hope that we shall not separate without doing something with these recommendations. Let us sit to-morrow and finish with the matter when it is fresh in our minds.

Professor GAIRDNER was willing to adopt this procedure.

Mr. BRUDENELL CARTER felt that they were in a better position to deal with these matters at once than they would be six, possibly twelve, months hence.

Sir WALTER FOSTER urged that they were at the far end of a long session, that what was wanted was the opinion of those who were not familiar with all the details rather than that of those who were, and that consideration of the report should be postponed.

Dr. PETTIGREW moved that the Council deal with the report on Friday and subsequent days.

Professor GAIRDNER seconded this amendment.

Sir DYCE DUCKWORTH said there was no doubt that if the general pronouncements of the committee were adopted they would be an exceedingly valuable guide to the examining bodies of the country. The subject was one of the most important parts of the work for which the Council met, and even now they were at least six months behind with it. It would be a great satisfaction to get it out of hand. They wanted to clear the way because there was the inspection of preliminary examinations, which should have commenced before this time. Many of them understood the details very much better now than could be expected of them six months hence.

Mr. TEALE thought that if the recommendations were important they were too important to discuss at the far end of the session.

Dr. GLOVER suggested that it would not be quite respectful to the committee to go on now. Considering the value of the report it should be postponed till next session and then be taken as the first business.

The PRESIDENT was of opinion it would be premature to force on a discussion now.

On a division the amendment had only six supporters, and Dr. Macalister's motion was then put and unanimously agreed to.

Public Health Examinations.

The next business was that of receiving reports from the

Examination Committee on the inspection of examinations in sanitary science of the following bodies: (a) the Conjoint Board in England; (b) the University of London; (c) the Conjoint Board of the Royal Colleges of Physicians and Surgeons in Ireland; and (d) the University of Dublin.

Sir DYCE DUCKWORTH proposed that all these reports and the similar reports presented to the Council at their session in November last, together with the provisional reports thereon prepared by the Examination Committee, should be referred to the Public Health Committee for consideration and report. He was happy to congratulate the chairman of the new committee, whoever he might be, on the fact that the reports that were being handed over were all brought up to date, for the Examination Committee had prepared a report on each of the reports of inspection.

Dr. BATTY TUKE seconded the motion, which was agreed to.

The Public Health Committee was then nominated as follows: Dr. Thorne Thorne, Dr. Batty Tuke, Sir Philip Smyly, Mr. Teale, Dr. Cameron, Dr. W. Moore, Dr. Church, Dr. McVail, and Dr. Haughton.

Dental Examination.

The new Dental Education and Examination Committee was nominated as follows: Mr. Carter, Mr. Bryant, Dr. Cameron, Sir Philip Smyly, Dr. Fraser, and Dr. Chas. Moore.

Registration of Students.

Sir DYCE DUCKWORTH presented a report from the Students' Registration Committee. He said it contained no matter that would excite attention—the work of registration was almost automatic.

The report was received and entered on the minutes.

The Pharmacopœia.

The PRESIDENT moved that the Council should place £2000 at the disposal of the Pharmacopœia Committee for the purpose of enabling them to proceed with the work of producing a new edition of the Pharmacopœia.

Dr. MACALISTER seconded the motion.

Dr. HERON WATSON suggested that the sum should be £3000.

Modified in accordance with this suggestion, the motion was agreed to.

A vote of thanks was then, on the motion, of Sir JOHN BANKS, accorded to the President, and this brought the proceedings of the session to an end.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—Bologna:

Dr. S. Salaghi has been recognised as *privat-docent* in Therapeutics.—Bonn: Dr. E. Schulze has been recognised as *privat-docent* in Neurology and Psychiatria.—Halle: Dr. F. Haasler has been recognised as *privat-docent* in Surgery.—Leipzig: Professor J. von Kries of Freiburg, a former assistant of Professor C. Ludwig, has been appointed to succeed him in the chair of Physiology. Dr. R. Kockel has been recognised as *privat-docent* in Pathological Anatomy.—Marburg: Dr. E. Behring has been promoted to the rank of Ordinary Professor of Hygiene. Dr. W. von Sobieranski has been recognised as *privat-docent* in Pharmacology.—Vienna: Drs. Chvostek, Max Herz and Norbert Ortner have been recognised as *privat-docentes* in Medicine, Dr. Salsmann as *privat-docent* in Ophthalmology, and Dr. Réthi as *privat-docent* in Laryngology.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—

At the annual general meeting of this society held on Monday, June 10th, the following were elected office-bearers for the year 1895-96:—President: David Hepburn. Vice-Presidents (resident): Ashley Gibbings, John Fairbank. C. J. Boyd Wallis; (non-resident) W. E. Harding (Shrewsbury), George Henry (Hastings), and J. F. Cole (Ipswich). Treasurer: S. J. Hutchinson. Librarian: W. A. Maggs. Curator: Storer Bennett. Editor of Transactions: Edward Lloyd-Williams. Honorary Secretaries: J. H. Mummery (foreign), J. F. Colyer (council), and Clayton Woodhouse (society). Councillors (resident): C. E. Truman, W. R. Humby, W. B. Paterson, Harry Baldwin, John Gartley, Cornelius Robbins, Sidney Spokes, Alfred Smith, G. D. Curnock; (non-resident) G. G. Campion (Manchester), J. McKno Acland (Exeter), J. H. McCall (Leicester), T. Arkövy (Budapest), A. W. W. Baker (Dublin), F. E. Huxley (Birmingham), Geo. Cunningham (Cambridge), C. B. Mason (Scarborough), and J. J. Andrew (Belfast).

THE triennial festival dinner in aid of the funds of the Royal Maternity Charity, of which the Queen is patron and the Duke of Argyll president, took place on Wednesday night at the Albion Tavern. Dr. Robert Barnes presided, and the Secretary reported that during the evening donations and subscriptions had been received amounting to about £800.

SIR JAMES CRICHTON-BROWNE, M.D., LL.D., F.R.S., will preside at the distribution of prizes to the Stepney Jewish Schools, to be held at the Queen's Hall, People's Palace, Mile End-road, on Monday next, at 7.30 P.M. The prizes will be distributed by Mrs. Adler, wife of the Chief Rabbi, and the proceedings will conclude with a gymnastic and calisthenic display by the pupils.

BATHING FATALITIES.—Although the bathing season has only recently commenced, many fatalities have already occurred. In the past few days—namely, during Saturday, Sunday, Monday, and Wednesday last—in the suburbs of London and the provinces, no less than fourteen boys and young men, and two men have lost their lives while bathing. Of the former it would appear none could swim, and of the latter, both men were seized with cramp, suddenly disappeared, and were drowned. At each recurring bathing season similar casualties occur, and are a striking testimony of the prevailing neglect of the art of swimming and emphasise the necessity of calling public attention to the fact.

At a meeting of the Society for the Study of Inebriety held on the 6th inst., the President, Dr. Norman Kerr, in the chair, it was resolved to memorialise Government to propose legislation, on the lines recommended by the Scotch Departmental Committee on Habitual Offenders, for the compulsory curative detention of habitual drunkards, for provision for the poor, and for the extension of the definition of "habitual drunkard" in the Inebriates Act of 1879 to excessive users of morphine and other drugs. The thoroughness of the inquiry was highly commended, and special mention was made of the three members of the committee having a medical qualification—the chairman, Sir Chas. Cameron, M.P., Dr. Farquharson, M.P., and the secretary, Dr. J. F. Sutherland. Surgeon-Major Pool, Dr. David Walsh, Mr. Hazell, and others took part in the discussion.

PRESENTATION.—At the meeting on the 7th inst. of the general committee of the General Hospital at Birmingham, which was also well attended by friends, Dr. W. F. Wade was presented with a testimonial in recognition of the valuable services rendered by him as physician to that institution. Mr. F. Everitt presided. Mr. J. B. Clarke (chairman of the Testimonial Subcommittee) stated that 106 subscribers had contributed, and the sum available was £261 11s. 6d. A silver tea-tray had been selected by Dr. Wade, on which was engraved the following inscription:—"Presented, with a cheque for £196 11s. 6d., to Willoughby Francis Wade, M.B., F.R.C.P., on his retiring from the office of physician to the Birmingham General Hospital, which he had filled for twenty-seven years, as a token of appreciation of his valued services to the institution. The cheque was generously given by Dr. Wade to the building fund of the New General Hospital. June 7th, 1895." The chairman, on making the presentation, stated that Dr. Wade's services to the medical charities of the city covered a period of forty years.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Whitsuntide Recess.

THE House of Commons, after a recess of exactly a week, resumed its session on Monday, June 16th. The House of Lords takes a recess of a little over a fortnight and will resume on Monday, June 17th.

The Factories and Workshops Bill.

In the present state of the law boys over thirteen possessing the necessary educational certificate can be employed at night in paper mills, ironworks, blast furnaces, and letterpress printing works, and in this Bill the Government proposed to raise the age to sixteen years. When the proposal was discussed in the Grand Committee on Tuesday, June 11th, Mr. Matthews, Sir Arthur Hickman, Sir J. Joicey, Mr. Whiteley, and a number of other members expressed objection to it, and as a compromise Mr. Asquith arranged to take the age of fourteen years as the limit, and to give the Secretary of State power to impose certain conditions as to the night work, conditions as to ventilation, hours worked, &c.

The Diseases of Animals in Ireland.

The Veterinary Department in Ireland has issued a report for 1894 with reference to the diseases of animals. The diseases with respect to which special powers are conferred by statute on the Lord Lieutenant and Privy Council in Ireland are cattle plague, pleuro-pneumonia, foot and mouth disease, and swine fever, but anthrax, rabies, glanders or farcy, sheep-pox, and sheep-scab are also dealt with under an Act passed last year and by Orders in Council. The Veterinary Department report that no case of cattle plague has occurred in Ireland since 1866, no case of pleuro-pneumonia since 1892, and no case of foot and mouth disease since 1884. Twenty-eight cattle were slaughtered as suspected of pleuro-pneumonia, but the post-mortem examination of the lungs by the officers of the department showed that the disease did not exist in any of these cases. The principal work of the department during the year had been connected with swine fever which had been prevalent in Ireland and caused serious losses. During the ten months of the year 1893 prior to Nov. 1st, when the Swine Fever Act came into force, only 196 outbreaks of the disease were reported in all Ireland, while in the fourteen months from Nov. 1st, 1893, to Dec. 31st, 1894, no less than 12,657 separate cases had been reported. In a large proportion of these reports the inspectors of the local authorities on visiting the places found that no disease existed; in many others when a suspected pig was slaughtered the post-mortem examination showed that the affection was not swine fever, but in 7929 instances the outbreak was confirmed by the examination of the viscera by the veterinary officers of the department. As to anthrax, only five outbreaks were reported in 1894 as compared with twenty-two in 1893, while as to glanders or farcy thirteen outbreaks were reported. The cases of rabies reported were 779 in number, or 355 more than in 1893. The report says in this connexion that the provision of the Rabies (Ireland) Order of 1894 authorising local authorities to pay compensation for animals suspected of rabies that are slaughtered by their direction has probably led to an increase in the number of reports, and that there is strong reason to believe that in a large proportion of the cases reported the animals were not really affected with rabies.

HOUSE OF COMMONS.

MONDAY, JUNE 10TH.

The Irish Prisoners at Portland.

Mr. William Redmond asked the Home Secretary whether Gallagher and others of the Irish prisoners at Portland were suffering from excessive ill-health, and if so, whether he would order a special medical inquiry to be held. Mr. Asquith, in reply, said that all the prisoners referred to, with the exception of John Curtin, were now in good health. The prisoner Gallagher was admitted into the hospital for anaemia on May 1st. He was discharged from the hospital on the 30th, having gained 4 lb. in weight and expressing himself as very well. The prisoner Curtin was at present in the hospital, and he had had a special inquiry made by Dr. Gover into his condition. He showed some improvement and his case was being carefully watched.

TUESDAY, JUNE 11TH.

The Condition of Aldershot Camp.

Mr. Alpheus Morton asked the Secretary of State for War whether several officers had been seriously ill caused by the insanitary condition at Aldershot; whether he was aware that they or their friends had been put to large expense in obtaining private medical attendance, and would he explain on what grounds the War Office refused to pay these expenses.—Mr. Campbell Bannerman replied that among the cases that had occurred at Aldershot among officers only those of enteric fever could be caused by insanitary conditions, and of this disease only four cases had occurred since Nov. 1st last. The origin of the disease was in all cases stated to be doubtful. Any officer whose illness was distinctly traced to the insanitary condition of his official quarters was indemnified for any medical expenses he might incur when an army medical officer was not available.

The Army Medical Staff in India.

Mr. Alpheus Morton asked the Secretary of State for India whether his attention had been called to the condition of the Army Medical Staff in India; whether the Medical Department was terribly undermanned; and, whether adequate arrangements were made for a reserve in case of emergencies like the Chitral Expedition.

Mr. Henry Foster replied that the establishment of the Army Medical Staff in India was considered sufficient for the requirements of the Army in peace and war, and there was no reason to suppose that it was "terribly undermanned," as assumed by his hon. friend.

Summer Clothing for the Police.

Mr. Asquith, in reply to a question put by Mr. Snape whether, as an example to the municipal and county constabulary authorities throughout the country, arrangements could be made to promote the comfort of the Metropolitan Police by supplying them with lighter clothing during the hot summer months, said that the matter had been frequently considered, and the opinion of the Commissioner and of the Chief Surgeon of the police was averse to the proposal. He undertook, however, to obtain a fresh report on the subject.

WEDNESDAY, JUNE 12TH.

Funeral Expenses of Children Bill.

On the motion of its sponsor, Sir Richard Webster, this Bill was withdrawn after having reached the Committee stage. The principal provision of the Bill was aimed at the insurance of children under two years of age, and Sir Richard Webster, in asking leave to withdraw the measure, said he had not sufficiently considered the interests of some of the best of the friendly societies. Mr. Abraham took the opportunity to condemn the Bill as an outrage on the feelings and aspirations of the working-classes. Several members suggested that there should be an inquiry before legislation on this subject was again attempted.

IN COMMITTEE.

Food Products Adulteration.

The Select Committee of the House of Commons on the Adulteration of Food Products, of which Sir Walter Foster is chairman, met on Wednesday, June 12th, and resumed the examination of witnesses.

Mr. John Williams, President of the Grocers' Association of Manchester and Salford, said that in 1892 there were a good many complaints about the fraudulent sale of margarine in Manchester and a vigilance committee was appointed to see to the matter. With the assistance of a solicitor they got up a number of prosecutions, but they received very scant encouragement from the authorities. In two cases a nominal fine was imposed, while in a third the accused person got off, and the Association had to pay costs to the extent of £5. He complained that while the corporation of Manchester authorities bestirred themselves with reference to excess of water in butter, they overlooked serious and systematic fraud in connexion with the sale of margarine. In his opinion, if the magistrate was assured that there had been fraud, he could not impose too heavy a fine, and in order to prevent fraud he would have all margarine sent out in certain shapes. The practice of having two counters, one for butter and the other for margarine, was no protection to the purchaser; on the contrary, it was made a means of fraud. Both butter and margarine should, in his opinion, be sold openly. The invoice should be considered as a warranty, and the person who gave it held responsible. With regard to mixtures of coffee and chicory he objected to the percentages being stated on the label. He thought the present label effective enough, but if he did anything to it at all it would be to prevent the use of other words than coffee and chicory upon it. Reverting to margarine, witness said he would have all margarine sold in oblong or brick-shaped blocks, tied up and marked in a particular way. He would not allow more than 6 per cent. of butter in margarine. It was necessary to make some allowance of butter, because he was informed that in every case there was a certain percentage of butter in margarine. He would have all butter and margarine examined at the port of entry by the officials there, travelling inspectors to visit localities and encourage local authorities to carry out the law, wholesale houses and manufactories inspected, and samples taken at hotels and restaurants.

Mr. William Jennings, President of the Bristol Grocers' Association, gave evidence with regard to coffee mixtures and cocoa, saying that the present labels were a sufficient protection to the public. When people bought coffee at 10d. or cocoa at 4d. per lb., they knew very well they were not getting pure coffee or pure cocoa. He took the same view with regard to mustard. In the case of pepper and ginger, he thought they should always be genuine, and that there was no need for adulteration. He had no wish to stamp out the trade in margarine, which, he thought, was a necessary article of food for people who could not afford to pay for butter, but he would put some limit on the power of mixing butter and margarine. He would also have inspection at the port of entry and imprisonment inflicted in case of repeated offence. If imprisonment did not stop fraud, then he would prohibit the colouring of margarine like butter.

Mr. Adam Morton Dunlop, President of the Glasgow South-Eastern Grocers' and Provision Dealers' Association, expressed the opinion that prosecutions in connexion with margarine should not be taken under the Food and Drugs Act, but under the Margarine Act. He said so because in Glasgow customers objected to use the word "margarine," and although they knew they were getting margarine asked for butter, or merely for "fivepenny" or "sixpenny," according to the price of the article. The result was that a grocer in Glasgow was liable to conviction under the Food and Drugs Act every day he opened his shop. Where there was deliberate intention to commit fraud, he did not think too severe a penalty could be inflicted. He did not think there were more than a very few dishonest traders in Glasgow or any part of Scotland, but these few gave a bad character to the trade. He would not allow margarine to be packed in kits or butts or casks identified with special kinds of pure butter, but would have a package for margarine. He objected to any interference with the practice of colouring margarine because it would drive the article out of the market.

Mr. Arthur J. Giles, secretary of the Grocers' Federation and the Metropolitan Butter Association, was also examined. He recommended the appointment of a board of reference, who would deal with such matters as the standard of purity, the colouring of margarine, and the question of what was injurious, and he suggested that on that board there should be representatives of such bodies as the Society of Public Analysts, the General Medical Council, the Grocers' Federation, the wholesale dealers and manufacturers, and Somerset House. He thought an appeal to Somerset House should be given in every case from the decision of the local analyst.

The committee then adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

- ALLAN, H., M.B., M.S. Aberd., has been appointed Medical Officer of Health to the Whaley Bridge Urban District Council.
 BAILEY, T. R., M.D., C.M. Edin., has been reappointed Medical Officer of Health for the Bilston District Council.
 BROSTER, A. E., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer of Health to the Wirksworth District Council.
 BROWN, OSMOND P., M.R.C.S., has been appointed Medical Officer of Health to Knighton Rural District Council.
 BUCHANAN, PETER, M.B., C.M. Glasg., has been appointed Medical Officer of Health to the Coleford Urban District Council.
 BUTLER, P., L.R.C.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Chiddingly Sanitary District of the Hambleton Union.
 CRAWFORD, DOUGLAS, M.B., C.M. Edin., has been appointed Assistant Honorary Surgeon to the Stanley Hospital, Liverpool, vice Smith, resigned.

- DAVIDSON, J., M.B. Lond., M.R.C.S., has been appointed Medical Officer to the Uxbridge Joint Hospital.
 ELLIOTT, R. H., M.B., B.Ch. Irel., has been appointed Junior House Surgeon to the Stanley Hospital, Liverpool.
 FINDLAY, G., M.B., C.M. Aberd., has been appointed Medical Officer of Health to the Campden District Council.
 GARDNER, HAROLD BELLAMY, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Assistant Anaesthetist to Charing-cross Hospital.
 GILLAM, T. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Saply Pitchard Sanitary District of the Marley Union.
 HANNAH, NATHAN, L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health to the Abram Urban District Council.
 HARRIS, WILFRED J., B.A., M.D., B.C. Cantab., has been appointed Junior House Physician to the National Hospital for the Paralyzed and Epileptic, Queen-square, vice Warrington, resigned.
 LITTLETON, PHILIP R., M.R.C.S., has been appointed Medical Officer of Health to the Ashbourne Urban District Council.
 LOCKWOOD, B. S., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Assistant Medical Officer to the Workhouse of the Leeds Union, vice Hirst, resigned.
 MARTIN, ARTHUR J., M.B. Lond., M.R.C.S., has been appointed Medical Officer for the Bloxwich Sanitary District of the Walsall Union, vice Somerville.
 MARTIN, J. T., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer to the Catholic training-ship *Clarence*, Birkenhead.
 MORON, WM., L.R.C.P., L.M. Edin., M.R.C.S., has been appointed Medical Officer of Health to the Matlock Urban District Council.
 PERCIVAL, TROS., M.R.C.S., has been appointed Medical Officer of Health to the Knottingly Urban Council.
 RISHLEY, STANLEY, M.D. Edin., has been appointed House Surgeon to the Rotherham Hospital and Dispensary.
 ROBERTS, EDWARD B., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., L.M., has been appointed Medical Officer of Health to the Hawarden District Council.
 ROBERTSON, JOHN, M.D. Edin., B.Sc. (Public Health), has been reappointed Medical Officer of Health for St. Helen's, Lancs.
 ROSE, F. L.D., F.R.C.S., has been appointed Honorary Dentist to the Stanley Hospital, Liverpool, vice Alexander, resigned.
 RUDH, CHAS. F., M.R.C.S., has been appointed Medical Officer for the Stalham Sanitary District of the Smallburgh Union.
 SKINNER, D. S., M.D. Brux., L.R.C.P. Lond., M.R.C.S., L.M., has been appointed Medical Officer of Health to the Willesden District Council.
 STEELE, JONATHAN, L.R.C.P. & S. Ed., has been reappointed Medical Officer to the Kidsgrove Urban Council.
 STODDART, W. H. B., M.B., B.S. Lond., has been appointed Senior House Physician to the National Hospital for the Paralyzed and Epileptic, Queen-square, vice Whiting.
 SUNDERLAND, OLIVER, L.R.C.P., L.M. Edin., M.R.C.S., has been appointed Medical Officer of Health to the Bexley Urban District Council.
 TAYLOR, JOHN W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health to the Methley Urban District Council.
 WALKER, B., M.B. Durh., M.R.C.S., has been appointed Medical Officer for the Ravenstonedale Sanitary District.
 WEBB, A. LISLE, M.R.C.S., M.R.C.P., has been appointed Resident Medical Officer to the National Hospital for Diseases of the Heart and Paralysis, Soho-square, vice Goldney.
 WILCOX, E. M.D., M.S. Edin., M.R.C.S., has been appointed Medical Officer for the Ashburton Sanitary District of the Newton Abbot Union, vice Brown, resigned.
 WILLIAMS, EDWARD, M.R.C.S., has been appointed Medical Officer of Health for the Aberayron Urban Sanitary District.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

- BOROUGH OF LOWESTOFT.—Medical Officer of Health and Medical Attendant at the Sanatorium for the Urban and Port Sanitary Districts of Lowestoft. Salary for the Urban Sanitary District, £100 per annum; for the Port Sanitary District, £20 per annum; and as Medical Attendant at the Sanatorium, £30 per annum. Applications to the Town Clerk, Lowestoft.
 BRADFORD INFIRMARY AND DISPENSARY.—Honorary Physician.
 CITY OF LONDON UNION INFIRMARY, Bow-road, E.—Resident Officer. Salary £450 per annum and unfurnished residence. Applications to the Clerk, Guardians' Offices, 61, Bartholomew's-close, E.C.
 DISTRICT INFIRMARY, Ashton-under-Lyne.—House Surgeon. Salary £90 a year and board and lodging.
 FLINTSHIRE DISPENSARY.—Resident House Surgeon. Salary £120 a year, with furnished house; rent and taxes free; also coal, light, water, and cleaning; or in lieu thereof the sum of £20 per annum. Applications to the Secretary, Board-room, Bagillt-street, Holywell, N. Wales.
 GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—Senior House Surgeon, for six months. Salary at the rate of £60 per annum, with board, lodging, and laundry in the hospital.
 KENT COUNTY LUNATIC ASYLUM, Barming Heath, near Maidstone.—Fourth Assistant Medical Officer and Pathologist, for two years, unmarried. Salary £175 per annum (rising £5 a year), with furnished quarters, attendance, coal, gas, garden produce, and washing.
 LONDON HOSPITAL, Mile End, E.—Medical Electrician.
 LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.—Senior Demonstrator of Anatomy. Salary by a percentage on fees.
 MANCHESTER ROYAL INFIRMARY.—Resident Medical Officer for one year, unmarried. Salary £150 per annum, with board and residence.
 NEW HOSPITAL FOR WOMEN, 144, Euston-road, N.W.—Medical Women, qualified as Clinical Assistants, for the Out-patient Department.
 NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—Junior House Physician for six months. Board and lodging (including washing) will be provided.

NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill, Stoke-on-Trent.—Assistant House Surgeon for six months.

POPULAR AND STEPHEN SICK ASYLUM DISTRICT.—Medical Superintendent for the Asylum at Bromley, Middlesex, E.—Salary £350 per annum, with rations, furnished apartments, washing, and service.

ROYAL GENERAL DISPENSARY, 25, Bartholomew's-close, London, E.C.—Physician.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo Bridge-road, S.E.—Clinical Assistant and Anaesthetist for six months. Salary at the rate of £30 per annum.

SHEFFIELD GENERAL INFIRMARY.—House Surgeon. Salary £120 a year, with board, lodgings, and washing, with a prospective advance of £10 per year for the second and third years. Also, Assistant House Surgeon for three years. Salary £80 per annum, with board, lodging, and washing.

SIR PATRICK DUN'S HOSPITAL, Dublin.—Assistant Surgeon for the Out-patient Department. No salary.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square.—Honorary Dental Surgeon.

UNIVERSITY OF ABERDEEN.—Examiners in Medicine.

VICTORIA HOSPITAL FOR CHILDREN, Queen's-road, Chelsea, S.W.—House Physician to the in-patients of this hospital. Honorarium of £50 per annum, and will be provided with board and lodging in the Hospital.

WANDSWORTH AND CLAPHAM UNION.—District Medical Officer for the No. 2 District of the Parish of Streatham. Salary £60 per annum, with fees for surgical operations and Midwifery. Such salary to include the cost of the provision of medicine, &c.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—Resident Assistant, for six months. Board, lodging, and washing provided.

WREXHAM INFIRMARY AND DISPENSARY.—House Surgeon. Salary £80 per annum, with furnished rooms, board, gas, coal, and attendance.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular in question.

STAMMERING.

To the Editors of THE LANCET.

SIRS,—In the interesting lecture on Impediments of Speech by Dr. W. S. Colman, reported in THE LANCET of the 8th inst., he says the stammerer "must try to vocalise If he stumbles over such a word as for he should think not merely of the voiceless letter *f*, but of vocalising the vowel *o* This method we owe to Dr. Wyllie." Allow me to say that the late Emil Behnke originated this method as far back as May, 1882, more than nine years before the first appearance in the *Edinburgh Medical Journal* of Dr. Wyllie's articles on "Disorders of Speech," the publication of which commenced in October, 1891. In April, 1891, Mr. Behnke was honoured by an invitation to read a paper before the South Wales Branch of the British Medical Association on "Stammering and other Speech Defects," and to describe the methods by which he had obtained such excellent results; and he afterwards lectured on the same subject to other assemblies of medical practitioners. In his lecture occur the following sentences: "Let the stammerer exaggerate his vowels at the expense of his consonants. The stammerer should therefore dwell on an easy syllable, prolonging the vowel of it." At the request of many medical men the lecture was published under the title, "Stammering: its Nature and Treatment." That Dr. Wyllie has also suggested the same plan as did Mr. Behnke before him, and the coincidence that the majority of Dr. Colman's opinions are identical with those of Mr. Behnke, prove how correct were his theories. I am, Sirs, yours obediently,

Karl's Court-square, S.W., June 10th, 1895.

K. BEHNKE.

Births, Marriages, and Deaths.

BIRTHS.

BURNETT.—On June 4th, at St. Albans-road, Watford, the wife of John Duncan Burnett, M.B., of a daughter.

CAIRD.—On June 5th, at 21, Rutland-street, Edinburgh, the wife of P. M. Caird, M.B., F.R.C.S. Edin., of a son.

ELAM.—On June 8th, at Addington House, New Barnet, the wife of W. H. Elam, F.R.C.S. Eng., of a son.

WILLIAMS.—On June 5th, at Holyrood House, Beckenham, Kent, the wife of J. Lawson Williams, M.D., of a son.

MARRIAGES.

BURTON—PERKS.—On June 6th, at St. Paul's, Burton-on-Trent, by the Rev. N. Jackson, M.A., vicar of Kasingwold, assisted by the Rev. F. H. Beaven, vicar of the parish, James Edward Burton, B.A. Cantab., B.Sc. Lond., head master of Kasingwold Grammar School, fourth son of Frederic Burton, of Knatebull-road, S.E., to Constance May, younger daughter of Charles Perks, M.R.C.S., L.R.C.P., of Burton-on-Trent.

ECCLIS—ANSTIE.—On June 12th, at the Baptist Chapel, Devizes, by the Rev. J. F. T. Hollowes, M.A., of Birmingham, William McAdam Eccles, M.B. Lond., F.R.C.S. Eng., of Harley-street, W., son of W. Soltau Eccles, Esq., of Upper Norwood, to Anna Coralie, second daughter of Edward B. Anstie, Esq., of Devizes.

EDGELOW—MATTHEW.—On June 12th, at St. George's, Hanover-square, William Ford Edgelow, M.D., of Braddonfield, Torquay, to Emily Jane, widow of the late Alexander Matthew, of Braddon Villa, Torquay.

LANGDON-DOWN—CLEVELAND.—On June 6th, at St. Thomas's Church, Portman-square, Reginald L. Langdon-Down, M.B., M.R.C.P., elder son of J. L. H. Langdon-Down, M.D., F.R.C.P., J.P., of Harley-street, to Jane Jarvis, eldest daughter of the late Lieut.-Colonel G. D. D. Cleveland, 98th Regiment.

LAWS—LUMBY.—On June 11th, at the Parish Church, Grantchester, Cuthbert Umfreville Laws, M.B., Dunelm, son of Wm. Geo. Laws, City Engineer, Newcastle-upon-Tyne, to Grace Margaret Bryham Lumby, daughter of Dr. Lumby, of Cambridge.

DEATHS.

ARMSTRONG.—On June 5th, Fergus Armstrong, M.D., of Appleby, Westmoreland.

CARRINGTON.—On June 10th, at the residence of her son, Dr. W. H. Carrington, 143, Lavender-sweep, London, Louisa Maria, widow of the late Mr. F. G. Carrington, of Gloucester, and mother of the late Dr. H. E. Carrington, of Guy's Hospital, aged 80.

CLARK.—On June 6th, at Brompton, William Clark, M.R.C.S., L.R.C.P., aged 38.

DEANE.—On May 7th, at Naini Tal, N.W.P. India, Surgeon-Major William Deane, F.R.C.S., aged 39.

HADDEN.—On June 6th, at St. Thomas's Hospital, London, John Hadden, M.D., of White Hall, Hampton Court, aged 53, for twenty-five years practising at Horncastle, Lincolnshire, and lately at Wilton Lodge, Norton, Kingston-on-Thames.

PARKER.—On May 29th, at Parrock-street, Gravesend, Alfred Edward Parker, M.R.C.S., aged 44.

PERKINS-CASE.—On June 11th, at Wilton Lodge, Croydon, P. W. Perkins-CASE, M.D., aged 41.

SILVESTER.—On June 4th, at Wellesley-road, Croydon, Simeon Talbot Silvester, L.D.S., R.C.S. Eng., aged 49.

TRIMMER.—On June 2nd, at Leytonstone, Essex, Henry Beesley Trimmer, M.D., late of Gamlingay, Cambridgeshire, aged 65.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE CASE OF MR. C. B. TOWNSEND.

THE following additional subscriptions have been received or promised, and are hereby gratefully acknowledged:—

Dr. John P. Henry ...	£0 10 0	Mr. Edwd. Gregory... ..	£1 1 0
Dr. T. Willoughby Cole ...	0 10 0	Dr. R. E. Foote	0 10 6
Mr. W. Clark	1 0 0	Dr. Garrod Thomas	3 0 0
Mr. E. C. Greenwood ...	5 6 0	Dr. H. Buss	0 10 0
Mr. Strangman Grubb ...	1 1 0	Dr. Chas. Gage Brown ...	1 1 0

Further subscriptions will be received and acknowledged by the Rev. H. Townsend, 41, King Henry's-road, South Hampstead, N.W.

UNDER the title "Æsculapian Love" the *St. James's Gazette* publishes the following humorous lines in satire of the valetudinarian tendencies of the younger generation:—

"O bid me not, Amanda, as a student of THE LANCET,
To meet you when the moon has tinged the sleeping earth with
The evening is traditionally fitting, but perchance it [gold;
Would bring about bronchitis, or at least a heavy cold.

"And, though we love each other as but few have loved before us,
We need no outward token of unalterable bliss;
Leave that to those less prudent; the authorities assure us
That very often microbes are transmitted by a kiss.

"Nor must you rush towards me to express your satisfaction;
It's true that fate has severed us for many a weary day;
But still, excitement, as you know, accelerates the action
Of pulse and heart in really quite a prejudicial way.

"I'll see you, then, at midday (please make sure the room is heated
To 60° or to 61°); we'll talk about the past,
And how our various ailments by our doctors have been treated—
When, by the way, Amanda, were you vaccinated last?

"And so we'll meet to-morrow; I will sing your favourite ballad
(For vocal exercises greatly benefit the lung),
And, having lunched discreetly off an hygienic salad,
We'll gaze into each other's eyes, and on each other's Tongue!"

An Interested Member &c.—A Licentiate of a Royal College of Physicians has certainly the right to describe himself as a physician. That is exactly what he is. He has not the right to prefix "Dr." to his name, because he is not a Doctor of Medicine.

J. W. W.—Our advertisement columns contain the names and business addresses of several manufacturers of such articles. Our correspondent should write to the different firms for catalogues or price lists.

A QUESTION OF UNPROFESSIONAL ACTION.

To the Editors of THE LANCET.

SIRS,—A, B, and C are neighbouring practitioners. A has held the appointment of medical officer to the workmen of a ship-repairing works for five years. A had a month's notice from the workmen. A deputation of the workmen waited on B and C asking them to become candidates for the appointment. On hearing of this A wrote B and C asking if they were candidates. B replied saying, as he said to the deputation, that he could not become a candidate unless there was a vacancy. C gave a similar answer to A. At the expiration of the month the secretary of the workmen wrote to B and C stating that the appointment was vacant. B and C applied as well as A. A accuses B and C of acting unprofessionally, which B and C repudiate. And assuming that A did canvass the votes of the workmen, did A act professionally? I am, Sirs, yours faithfully,

June 12th, 1895.

X. Y. Z.

* A, having received a month's notice, was right in considering that the post was not vacant until the month had expired. We do not see that there was any concealment on his part of the fact that the post would be vacant at the end of the month, and such concealment was obviated by the action of the workmen. If it is suggested by our correspondent's letter that B and C were prevented from canvassing the constituency by representations made to them by A, who himself did canvass the constituency, A's good taste might be questioned. But if A merely signified during his month under notice his willingness to continue to hold the appointment, possibly under altered conditions, his conduct cannot be impugned. When the secretary at the expiration of the month formally told B and C that the appointment was vacant, they were clearly, on the facts before us, at liberty to apply for it. Our correspondent will recognise that our answer is strictly based upon his representation of the case.—ED. L.

THE INFLUENCE OF THE ADMINISTRATION OF CHLOROFORM UPON THE COURSE OF PHTHISIS PULMONALIS.

To the Editors of THE LANCET.

SIRS,—Having had under observation a case of phthisis pulmonalis in which a surgical operation was performed, chloroform being administered, I am anxious to know if in such cases your readers have noticed any improvement in the lung condition or diminution in the number of tubercle bacilli in the sputum subsequently to the use of the anæsthetic. I am, Sirs, yours truly,

St. Leonards, June 5th, 1895.

EDWARD SAMUEL LEE, M.D.

"ANTITOXINE."

THE British Antitoxine Manufacturing Company have appealed to us to support their use of a term for the product they supply—the properties of which are said to be those of a powerful antipyretic and analgesic—on the ground that the reason for our previous protest no longer obtains. We doubt, however, whether it is the fact that "diphtheria antitoxin" has had its day. On the contrary, we believe that it is still on its trial, and have always held that such a trial must necessarily be a prolonged and patient one before it can be proved to be ineffective. We must therefore still regret this confusion of nomenclature, although we are glad to be informed that the drug "antitoxine" is obtaining an assured reputation. As that is the case it shows that there is not much risk in practice of confounding two remedies so similar in name but so unlike in action.

Newport.—The results to be obtained by the adoption of the Infectious Disease (Notification) Act largely depend upon the means available in the district for utilising the information when acquired; and amongst these means the provision of some hospital accommodation for first attacks of infectious diseases, and means of disinfection, occupy a foremost place. But, even apart from these, very useful work can be done by way of advice, disinfection, the control of school attendance in the case of children living in infected houses, and the like. And there is the further advantage that the mere knowledge of the existence of infectious disease in itself serves as a stimulus to sanitary authorities so to organise their districts that they may prevent the spread of infection. For these various reasons we advocate the adoption of the provisions of the Act in question.

Veritas.—The matter is not under discussion in our columns at the present time, so that our correspondent's communication somewhat beats the air.

Interested.—It is absolutely impossible. The story is a common hoax.

"ALLEGED TOUTING BY A PUBLIC VACCINATOR."

To the Editors of THE LANCET.

SIRS,—In your issue of May 18th you answered a letter of mine with regard to certain alleged irregularities on the part of a public vaccinator. Acting on your advice, I wrote to the Local Government Board, and have received the enclosed reply. Having drawn the attention of this public vaccinator and his principal to your answer, they repudiate any charge of unprofessional conduct, and state that "the conduct denounced by yourself and the Editors of THE LANCET is equally abhorrent to themselves. Further, this public vaccinator admits that it is his custom to call on patients and ask "if they wish to have their children vaccinated publicly or privately," and that "the orders under which I act are to visit all cases that are on my list as needing vaccination, and residing within two miles of my residence." While I must believe that technically this public vaccinator is correct and is acting more or less according to "orders" received from the local body who elected him; and since both he and his principal express their abhorrence at anything which you would call unprofessional, I shall be obliged if, having considered this matter from this public vaccinator's own statements as herein given, you will kindly express your opinion once more.

I am, Sirs, yours faithfully,

June 12th, 1895.

C. H. E.

[Enclosure.]

Local Government Board, Whitehall, S.W.

11th June, 1895.

SIR,—I am directed by the Local Government Board to advert to your letter of the 27th ultimo, and, in reply, I am to state that the Board have no power to prevent Dr. — from adopting the practice referred to therein.—I am, Sir, your obedient servant,

C. H. E., Esq.

ALFRED D. ADRIAN, Assistant Secretary.

* We found it our duty upon our correspondent's previous communication to state our opinion that the conduct of the public vaccinator was indefensible, and if persisted in should be reported to the Local Government Board. The Board, it would seem, have no power to interfere, but, noting the public vaccinator's abhorrence of anything that has the appearance of toutting, we venture to hope that the limitations of the Government office will not affect his conduct, and that he will abstain from an interference with the patients of a fellow-practitioner, which we consider most unfortunate, and, as we have already said, quite unprecedented.—ED. L.

"THE SWEATING OF MEDICAL MEN."

To the Editors of THE LANCET.

SIRS,—I have noticed some recent correspondence on the "sweating" of medical men by medical aid societies. Can we be surprised at the laity holding our services so lightly when we ourselves treat them as though they were not worth much, as evidenced by advertisements for locum tenens where "a comfortable home and railway fare" are offered in return for the charge of a practice? Two or three such advertisements are to be seen in the current number of THE LANCET.

I am, Sirs, yours obediently,

June 3rd, 1895.

X.

"UTERINE STEMS."

To the Editors of THE LANCET.

SIRS,—I waited for the next issue of THE LANCET before replying to your strictures upon my letter in the issue of June 1st, in case any other medical man might also criticise my letter, but since no one has done so I now reply to you. First, you accuse gynecologists of the present day of the performance of operations upon ante-flexed uteri on "the false pathology which attributed an altogether exaggerated, not to say imaginary, importance to the necessity of keeping the axis of the uterus straight." I am bold enough to think that gynecologists know sufficient of the pathology of ante-flexed uteri to justify their actions, and perhaps I may be pardoned by you for thinking that intra-uterine stems are used for other purposes than keeping the axis of the uterus straight. Then next your remark, "It is difficult to understand how anyone can suppose that applications to the endometrium through a hole in the centre of a stem pessary can have any good effect on salpingitis." Surely no one will dispute that the nearer one approaches the seat of disease the greater will be the chance of cure. Then comes the sentence which affects me more closely, "on the other hand, there is no doubt whatever that endometritis, metritis, perimetritis, salpingitis, ovaritis, and death have been caused by the use of intra-uterine stems." True, death does sometimes follow even the simplest operation, but since I have used uterine stems in no less than 200 cases without even the shadow of death following, it will take something more than the voice of THE LANCET before I shall feel justified in deterring patients from the many benefits accruing from the use of the stems. Then, Sirs, with regard to your translation of "i.e.," "I do not know if it is intended for a joke, but if so I certainly think you who print "death" in italics would do well to refrain from associating a joke with death. No one values criticism more than I, and I sincerely thank all who trouble to point out my errors.

I am, Sirs, yours faithfully,

Peckham, June 11th, 1895.

ROBERT HUGH HODGSON.

Mr. H. George.—The average experience of the profession in regard to a preparation cannot well be gauged. Many may not use it; many may use it only so little that their report would not be weighty; and many may use it much and yet never report upon it. We have spoken well of the preparation. Of the book alluded to by our correspondent we know nothing.

R. C.—1. "A Guide to the Examination of the Urine," by J. Wickham Legg, F.R.C.P. Lond., &c.; Seventh Edition, edited and revised by H. Lewis Jones, M.A., M.D. London: H. K. Lewis, 1893.—2. Any philosophical instrument maker.

Mr. W. Henry Kesteven is thanked for his interesting communication. If we are able to accede to his request we will communicate with him.

"HOMES FOR THE DYING."

To the Editors of THE LANCET.

SIRS,—H. A. B. will find such an institution as he requires in the Hostel of God, 82, The Chase, Clapham, S.W.—a "free home for the dying," served by the St. James's Servants of the Poor. Persons of both sexes and of every class are taken in, and, though in charge of a Church of England Sisterhood, no distinction is made as to creed. Your correspondent should write to the mother superior to inquire if there is a vacant bed for his old servant. There is not much room in the present temporary premises; but the sisters are now appealing for funds in order to build a permanent hospital.

I am, Sirs, yours faithfully,

Kensington Court, W., June 8th, 1895.

ATHELSTAN RILEY.

SWEATING EXTRAORDINARY:

To the Editors of THE LANCET.

SIRS,—The underpaying of assistants in the profession is not unknown. The following, however, fairly earns the palm. A certain apothecary and surgeon keeps a qualified man to manage a branch practice, six miles away from headquarters, for the magnificent pittance of £30 per annum and board. Surely, a more unqualified assistant gets more. The above manager does all the work, and there are no extras whatsoever.

I am, Sirs, yours faithfully,

June 10th, 1895.

DISGUSTED.

UNFERMENTED WINE.

To the Editors of THE LANCET.

SIRS,—I heard the statement made recently at a church meeting that the unfermented wine used at the sacraments was not the juice of the grape, but merely some kind of fruit juice extracted from, e.g., raspberries. Could any of your readers kindly inform me if this is really so; and, if not, give me the name and address of some firms who make *bond-fide* grape wine (unfermented, of course)?

I am, Sirs, yours truly,

June 11th, 1895.

VINUM.

THE OXYBROMIDES OF MERCURY.

To the Editors of THE LANCET.

SIRS,—Can any of your readers kindly inform me where I can obtain solutions of the oxybromides of mercury, arsenic, &c., as used in the United States with marked success?—I am, Sirs, yours faithfully,

June 12th, 1895.

S. H.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY.—ROYAL METEOROLOGICAL SOCIETY (22, Gt. George-st., Westminster).—7.30 P.M. Mr. Richard H. Curtis: Hourly Variation of Sunshine at Seven Stations in the British Isles.—Mr. Henry Harries: The Frequency, Size, and Distribution of Hail at Sea.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover-sq., W.).—8 P.M. Mr. W. C. Bosanquet: On the Anatomy of Nyctotherus Ovalis.—Dr. A. Bruce: A New Microtome.

NORTH-WEST LONDON CLINICAL SOCIETY.—8.30 P.M. Clinical Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 1 P.M., Mr. R. M. Gunn: Cataract.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Mr. G. C. Wilkin: Nasal Polypi.

TUESDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Percy Smith: Insanity with Syphilis; Insanity with Organic Brain Disease.

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Gowers.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—5 to 6 P.M. Dr. Morgan Dockrell: Sarcoma.

LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 8 P.M., Mr. A. Q. Silcock: Secondary Glaucoma, with Illustrated Cases.—Hospital for Skin Diseases, Blackfriars, 1 P.M., Dr. Payne: Syphilitic Affections of the Skin.

THURSDAY.—LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Gt. Ormond-st., 3.30 P.M., Dr. D. B. Lees: Cases from the Medical Wards.—National Hospital for the Paralyzed, Bloomsbury, 2 P.M., Dr. Tooth: Diseases of Cranial Nerves.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Dr. Frederick Taylor: Cases in the Wards.

FRIDAY.—LONDON POST-GRADUATE COURSE.—Bacteriological Laboratory, King's College, 3 to 5 P.M., Prof. Crookshank: Erysipelas and Suppuration.

SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Hyslop: Insanity with Cardiac Disease, Gout, &c.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—5 P.M. Dr. Morgan Dockrell: Eczema (treatment).

During the week marked copies of the following newspapers

have been received:—Glasgow Herald, Sussex Daily News, Brisbane Telegraph, Western Daily Mercury, Cape Times, Bombay Gazette, Falkirk Herald, Pioneer Mail, Hong Kong Telegraph, Times of India, Express and Star (Wolverhampton), Newcastle Chronicle, Weekly Times and Echo, Ayrshire Post, Hull News, Rochdale Observer, Hampshire Independent, Birmingham Mail, Cork Constitution, Scotsman, Buzler, Brighton Gazette, Bristol Mercury, Architect, City Press, Liverpool Daily Post, Hull Daily Mail, Leeds Mercury, Temperance Chronicle, Yorkshire Post, Liverpool Mercury, Pulman's Weekly News, Bury Guardian, Dumfries Standard, Montreal Daily Herald, West Middlesex Standard, Mining Journal, Reading Mercury, Weekly Free Press and Aberdeen Herald, Sanitary Record, Local Government Chronicle, Devsburry Reporter, Surrey Advertiser, Dover Express, Crewe Guardian, Darlington Echo, Public Health, Guy's Hospital Gazette, Isle of Wight Express, Morning Leader, Oswestry Advertiser, Dundee Courier, Local Government Journal, Courrier de la Presse, Kent Weekly News, Citizen, Argus (Melbourne), Portsmouth Times, County Council Times, Birmingham Daily Post, Southampton Observer, Whitehall Review, Westmorland Gazette, Hertfordshire Mercury, &c., &c.

Communications, Letters &c. have been received from—

- A.**—Dr. Albano, Bucharest; Surg.-Capt. S. G. Allen, Woolwich; Aberdeen University, Secretary of; Ashton-under-Lyne District Infirmary, Secretary of; Achilles, Lond.
- B.**—Dr. Fletcher Beach, Lond.; Dr. D. C. Black, Glasgow; Dr. J. Braithwaite, Leeds; Dr. W. J. Bell, Appleby; Dr. E. Bielley, Bruges; Dr. A. O. Bobard, H.M.S. *Tyne*, near Albany; Mr. A. Wynter Blyth, Lond.; Mr. Lennox Browne, Lond.; Mr. F. H. Bate, South Wimblesdon; Mr. L. M. Bowen-Jones, Carmarthen; Mr. T. B. Browne, Lond.; Messrs. W. V. Bowater and Sons, Lond.; Messrs. Burroughs, Wellcome, and Co., Lond.; Messrs. Blondeau et Cie., Lond.; British Medical Association, Hon. Secretary of; Bury Dispensary Hospital, Secretary of; Bradford Infirmary, Secretary of; British Castor Co., Lond.; Bryant Press, Toronto; Benedict, Lond.
- C.**—Dr. J. A. Campbell, Carlisle; Dr. J. G. Connal, Glasgow; Dr. L. J. G. Carré, Lond.; Mr. A. H. Cheate, Lond.; Mr. R. A. Caldwell, Southampton; Mr. W. R. Culling, Lond.; Mr. H. N. Custance, Lond.; Messrs. E. Cook and Co., Lond.; Cortland Wagon Co., Lond.; Central School of Chemistry, Lond.; Catholic, Lond.; Charing-cross Hospital, Secretary of.
- D.**—Dr. P. W. Dlack, Bury; Dr. T. Dutton, Lond.; Mr. W. Drewitt, Kingston-on-Thames; Mr. W. Defries, Lond.; Mr. J. Downes, Lond.; Mr. W. G. Dickinson, Lond.; Messrs. Domerol and Co., Lond.; Messrs. Dawson and Sons, Lond.; Messrs. Driscoll, Lennox, and Co., Lond.; Sir P. Dun's Hospital, Dublin, Secretary of; Dorchester Asylum, Medical Superintendent of.

The Croonian Lectures,

BEING A

CONTRIBUTION TO THE HISTORY OF
THE RESPIRATION OF MAN.*Delivered before the Royal College of Physicians of London on
June 18th, 20th, 25th, and 27th.*By W. MARCET, M.D. EDIN., F.R.C.P. LOND.,
F.R.S.

LECTURE I.

Delivered on June 18th.

MR. PRESIDENT AND GENTLEMEN,—Allow me to begin by returning my best thanks for the honour of being called upon by this College to deliver the Croonian Lectures for the present year. In these four lectures I propose to draw your attention to certain phenomena of human respiration. As far back as 1876 I was led, while mountaineering in the High Alps, to inquire into the influence of altitude on respiration; this work was continued every summer till 1880. The inquiry showed clearly that there was a great deal more to be done on the subject of human respiration; and through the kindness of Professor Schäfer, a laboratory having been placed at my disposal at University College, the work commenced in the High Alps was continued in London, with the aid of assistants, from the year 1883 to the present time. I propose in this first lecture to treat of the relations of the oxygen breathed with the life of the tissues; the second lecture will be devoted to the various forms of respiration in man; the third to the influence of volition on respiration; and the fourth to respiration carried on under exceptional circumstances, concluding with remarks of a more strictly medical character.

THE VITAL ENERGY AND CHEMICAL ACTION WITHIN THE
LIVING BODY.

Vital energy, vital force, or vitality, the cellular life of Virchow, may be defined as power or energy existing in the cell and radiating from it. This cell has oxygen as part of its molecular constitution, and with the aid of this oxygen is constantly undergoing change or metabolism with more or less energy, according to age, health, &c. It might be considered at first sight as if the test of vitality is the degree of power with which life clings to living organisms—such, for example, as seeds. Reliable information on this subject is to be found in *Nature Notes* for 1895, where it is stated by Dr. Carruthers that forty years ago Robert Brown succeeded in obtaining the germination of seeds of the *Nelumbium water lily*, which had been preserved in boxes for fifty years in Sir Hans Sloan's collection and another 100 years in the herbarium of the British Museum. I am much indebted to Dr. Carruthers' kindness in showing me those seeds preserved in acid, which had sprouted to the height of several inches. Dr. Peter of Göttingen has succeeded in obtaining the growth of seeds from the soil of a dense wood with trees 100 or 150 years old; he has also shown that the seeds of many field plants retain their vitality for considerably more than half a century. The vital resistance of seeds is more-over illustrated by the fact that they have been exposed to the greatest degree of cold obtainable by artificial means without losing their power of growth. These remarkable phenomena might possibly find an explanation in the following considerations. Life is a contest between vital energy and that other energy known as chemical decomposition. The instant an animal dies chemical decomposition comes into play, and the first change to take place is a combination of the oxygen, which is part and parcel of the molecular tissue. Once that oxygen gone, recovery of life is impossible.

It has been observed that in the case of animals one of the first decompositions to set in has for its result an acid state of the muscles, this acid being looked upon by Catherine Schipiloff from her experiments as the cause of rigor mortis. If we now return to seed life we shall find that it may be protracted, as it were, indefinitely under conditions which entirely check decomposition. The seeds of the *Nelumbium speciosum*, preserved for 150 years, had dried up and undergone no

No. 3747.

fermentation, and those cultivated by Dr. Peter had clearly found in the soil some preserving or sterilising material. It is but natural to conclude that a molecule of wheat, or of any other seed under such conditions, would retain its oxygen, though without being able to make use of it because of the absence of moisture and probably also of certain bacilli which have been found necessary to vegetable growth; hence the seed was not dead, but its life remained in a potential form, or under the form of vibrations too weak to produce any other effect than maintain themselves. So long as oxygen is present as a molecular constituent these vibrations will continue, but they will cease the instant this oxygen has disappeared. It cannot be said that the vitality of seeds is great, but only that seeds under certain atmospheric conditions are not acted upon by those chemical forces known to decompose vegetable tissues. Given an animal suddenly placed in a state resembling death, but in which it could retain its combined oxygen, would it not be possible to maintain its life in abeyance and ready to be restored on a return to favourable circumstances? The experiments of Raoul Pictet, the physicist who was the first to liquefy air, appear to give an affirmative reply to this question. In his experiments on fishes he has rapidly frozen them so hard that, according to his statement, they were in a state allowing of their being snapped asunder like a stick, and yet they have recovered life when very gradually thawed. It will be seen in the course of this lecture that when fish are frozen up and completely embedded in the ice during a winter's frost they cannot be brought to life again; hence it appears that the essential condition for the preservation of life is that the fish shall be frozen so rapidly that decomposition cannot possibly commence. Indeed, it is reasonable to conclude that, in Pictet's experiments, the molecules of tissue were frozen with their oxygen before they had time to dispose of it, and that this oxygen reacting on the molecules of tissue under favourable circumstances brought the fish to life, exactly as it happened that the reaction of oxygen in the seed brought the seed to life after life had been quiescent for fifty, or perhaps hundreds of, years.

As already stated, no phenomena of metabolism can take place without the interference of oxygen or atmospheric air. The amount of air or of atmospheric pressure required may certainly vary within wide limits, and we all know that with training and slow transition from the seaside to lofty mountain stations a considerable state of adaptation may be obtained. The action of oxygen in the living body, though, so far, very obscure, is a most interesting study, and first I shall hope to be able to show in a conclusive manner that it is not the oxygen in the atmosphere which by offering itself to the tissues brings about the tissue changes, but because the tissues are undergoing change they require and resort to the oxygen of the atmosphere; hence the more active the change the more oxygen required, and *vice versa*. It is often thought that more carbonic acid is formed when an increased volume of air is voluntarily breathed. This is not so, the excess of carbonic acid given out from the lungs being due to the emission of some of the carbonic acid normally present in the blood and not to increased combustion, except a very small amount for the extra muscular work of forced breathing. One of the several objects of oxygen is to produce heat; some of this heat being transformed into motion, is not perceptible by the thermometer, while another portion manifests itself as heat and can be directly observed. In cold-blooded animals the heat produced is entirely transformed into motion, but this is not the case with warm-blooded animals, which have an excess of heat ready for use; the latter find, therefore, in their bodies a large supply of power wanting in the former. If the production of heat is so intimately connected with life that life cannot exist in an active form without it, what is the essential nature of heat? Physicists regard this condition of matter as the result of a vibratory motion of its ultimate molecules, very feeble but very rapid, which is transmitted through the intermolecular and interplanetary spaces by the ether of space. From this view the warmest bodies will be those whose molecules vibrate with the greatest speed and amplitude—bodies as they become warm or cold merely gain or lose motion. Since in the living body heat is continually produced, the molecular vibrations producing it are ever at work; this formation of heat, which is due to the reaction of oxygen on organised matter, may therefore be looked upon as the very fundamental condition of life. If oxygen is thus indispensable to life, it must be within

B B

takes place in a few minutes, the temperature in the centre of the body remaining nearly constant to the end of this struggle for life. Fishes, frogs, batrachians, and ophidians resist freezing at temperatures varying from 4° to -22° ; they usually die at a lower temperature. The length of time the animals were exposed to the cold is not stated, and this must be an important factor. Raoul Pictet, in one of his lectures, exhibited to his audience a number of gold-fish, pike, and frogs frozen, and in the following lecture these same fishes, having been slowly thawed, were shown living and well. In the *Pall Mall Gazette* of March 23rd, 1891, an apparently authenticated case is quoted of a small fish which had survived six or seven months' enclosure in ice stored in an icehouse at Godalming. I have myself had an opportunity this last winter of observing gold-fish which had been caught in the ice. In every case in which the fish was completely embedded in the ice it showed no signs of life on thawing. One of the fish was only partly encased in ice, and had a small quantity of water left round it; when examined it appeared lifeless, but after a time it recovered perfectly. On another similar occasion the fish showed signs of life, but failed to recover. These observations apparently show that, if not absolutely embedded in the ice, the life of fishes can be held in abeyance for a time at a temperature close to freezing, but for how long I cannot tell. Following up my contention in this first address, these experiments show that the maintenance of the molecular vibration or motion of life requires very little heat in cold-blooded animals, and it may be concluded that at such a low temperature as 4° the heat is just sufficient to keep up life in the feeblest possible way. If the return of life movements be disturbed by too great an accession of heat, the vibration is immediately arrested, and a most careful handling is required to restore life to its full activity. At the beginning of this address I remarked as a proposition to be proved that it is not oxygen which by offering itself to the tissues brings about tissue change, but that the tissues make a call—a demand—on the atmospheric oxygen. In favour of this view the influence of cold on vitality was considered, and it was shown that cold up to a certain limit increased the vitality, but beyond that limit produced an opposite effect.

We have now to consider a state of life which to my mind bears some relation to the increased production of carbonic acid in the body from an accession of cold—I mean muscular exercise. The successive phenomena in muscular contraction are as follows. First, volition towards exercise produces an increase in the volume of air breathed, which occurs immediately before contraction or simultaneously with its commencement. At the same time, as will be shown in my third lecture, a certain amount of oxygen is apparently absorbed in the motor centres of the brain corresponding to that muscular exercise. An excess of carbonic acid is now expired, which at first obtains its oxygen from that contained within the muscles, and in proportion as this is used up the oxygen required is taken from the air breathed, the muscles at the same time charging themselves afresh with oxygen from the atmosphere. A number of experiments I made confirm this view. I must also state that we do not know by what process the carbonic acid is formed. The mode of exercise adopted in my experiments was raising the feet alternately 66 times per minute to a height of about 4 inches, in keeping with the striking of a metronome. The air expired was collected during successive periods and analysed. In the first period of three minutes the oxygen consumed from the air amounted to 719 c.c. per minute, in the second period of three minutes the experiment was lost, the third period of three minutes gave 770 c.c. of oxygen consumed per minute, the fourth 834 c.c., the fifth 799 c.c., and the sixth period of three minutes 775 c.c. From these figures it will be seen that during the first three minutes of exercise the oxygen consumed was only 719 c.c. per minute, although the heat required was the same as after six minutes or nine minutes, when much more oxygen was consumed from the air; hence it cannot be doubted that the muscles drew upon their molecular oxygen to a marked extent. These experiments were made on a former assistant. A series of experiments on myself, and another on my present assistant, gave corresponding result.

The connexion of exercise with respiration will be more fully inquired into later; in the meantime, if the amount of oxygen consumed by the body is a measure of the activity of the tissue change then exercise will be a means of keeping up and exciting the life of tissues, and thereby giving them

additional power to resist any abnormal change constituting disease. The overdoing of exercise is baneful in a great measure because of the difficulty the body will experience in obtaining from the air sufficient oxygen for the work, but perhaps as much also on account of the trouble required to rid the blood of the excess of carbonic acid formed which accumulates in the circulation. Muscular exercise is generally looked upon as raising the temperature of the body, although it may also be attended with a cooling effect; and this leads me to consider the question of the body temperature in the act of ascending. But before entering on this subject allow me to offer a few remarks on the methods in use of testing the temperature of the body.

In 1838 I had occasion to enter into a controversy with a Swiss gentleman, Dr. Vernet, who published results he had obtained from taking his temperature while engaged in mountaineering. He maintained that the only correct method of estimating animal heat was by means of a thermometer introduced into the rectum. Being in the habit of taking temperatures under the tongue, a method in general use clinically, I was anxious to ascertain the accuracy of Dr. Vernet's assertion. We accordingly together ascended the Dôle, one of the highest points of the Jura, and on nearing the summit, about 4000 feet in height, we found that with both of us there was a distinct rise of the rectal temperature. This experiment was not, in my opinion, conclusive, as in the act of climbing the blood, from the effect of gravity, must accumulate in the hæmorrhoidal vessels, leading to a state of congestion, and thus to a rise in temperature. The question, however, could only be settled experimentally. Five simultaneous observations of rectal and sublingual temperatures on different days while resting quietly in bed gave a mean excess of 0.3° F. in favour of the rectal temperature, while very moderate exercise, such as slowly walking about my room, produced a rise of the rectal temperature decidedly in excess of that observed under the tongue. Three experiments gave differences of 1.3° , 0.9° , and 0.8° , or a mean difference of 1.0° excess for the rectal temperature, and this was merely from moderate walking exercise in the room, and could not have been due to a general increase of temperature throughout the body; hence it appears that though there may be a very slight increase of the rectal over the sublingual temperature, when taken under circumstances affecting the temperature in both regions equally, still the moment a person is standing or walking, the rectal temperature is increased notably beyond the sublingual, which is simply due to a state of congestion produced by gravity. There remains the possibility of the cold in high altitudes acting through the submaxillary region and thus reaching the under surface of the tongue. To clear up this point I applied pieces of ice under the chin while the bulb of the thermometer was maintained under the tongue. On two occasions there was a perceptible rise in the temperature the moment the ice was applied, a phenomenon also observed by Raoul Pictet in his experiments on the application of cold to animals, and this was followed by a slight fall; the fall in three experiments amounted to 0.2° , 0.6° , and 0.5° in the course of from thirty to forty-eight minutes; therefore the application of ice to the submaxillary region affected but very slightly the sublingual temperature. The temperature of the body while ascending has been for a long time past subject to discussion. In 1865 Professor Marc Dufour, in his inaugural dissertation to the medical faculty of Zürich, stated from experiments made on himself that in the act of ascending the temperature of the body falls rapidly by about 0.4° . Another gentleman, Professor Fick, has observed the same phenomenon; many observers find that the body temperature is slightly increased by muscular exercise. In 1869 I began to give attention to this subject, and invariably found that my temperature fell while ascending, the extent of the cooling being dependent chiefly on the time which had elapsed since the last meal was taken, and to a less extent on altitude and atmospheric temperature. In general the fall of temperature was most rapid when ascending quickly, while fasting and perspiring freely. These inquiries were followed closely by those of Professor Lortet of Lyons, who obtained similar results. The observations of Dr. Clifford Allbutt, F.R.S., with three exceptions, gave results opposed to ours. Many other reliable observations have been published which seem to contradict one another. Thus Professor F. A. Forel of Lausanne found that the muscular work of ascending raised the body temperature; Mr. Gay of Strasburg observed a decrease of temperature on ascending, and the same

phenomenon was observed by Professor Ray Lankester. Hence it must be concluded that the influence of climbing on the temperature of the body varies with different persons. Some in thorough training, young, perspiring but little, and consuming as a rule a large amount of oxygen, or developing much heat under ordinary circumstances, will observe their temperature to rise in the act of ascending; others, who develop less heat, will generate just the amount they require for the exercise, but, the cold air and perspiration cooling the body, its temperature will fall below the normal.

The Bowman Lecture

ON

SUBJECTIVE VISUAL SENSATIONS.

*Delivered before the Ophthalmological Society on
June 14th, 1895.*

By W. R. GOWERS, M.D. LOND., F.R.S.,

CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; PHYSICIAN
TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

MR. PRESIDENT AND GENTLEMEN,—I count it no small honour to be one of the links of the chain of "Bowman Lecturers"—a chain which connects the recent past, and also the days that have already faded in the distance, with a future that will be, we hope, remote. Thirty-five years ago the names of Todd and Bowman were those of the makers of some, and the framers of much, of the physiology then current. Their names were on the lips of teachers in connexion with discoveries and work which then seemed distant to the student who made his first entry in the world of science. They seemed so much part of the past that it was almost a shock to learn that, though one of the illustrious pair had ceased from his labours, the other was not only an active worker, but was the leading ophthalmic surgeon of Europe. When, in after years, I came to know him personally, although but slightly, his personal characteristics impressed me as the very ideal of refined mental power, combined with quiet earnestness and with the courtesy that is born of perfect kindness—all expressed in a face and manner which once seen no memory could lose. It will always be a source of satisfaction to me to remember that, though the suggestion would probably soon have been made by another, I had the privilege of directing the attention of the Council to the fitness of connecting the name of Bowman with the Ophthalmological Society by the establishment of this Lecture, that the suggestion bore immediate fruit, and that it was a source of pleasure to him we thus honour, and by which not less are we also honoured. Alas, the lecture is now delivered to his memory, but it is pleasant to think that the society did not postpone its establishment until the time had passed when it could give pleasure to him to whom the expression of regard was given. Is it not sad that so often the living are only awakened to a sense of that which should be, by the death which makes it a satisfaction only to those who render? Although the Bowman Lecture is now only a memorial, the memory which it keeps up is still a vivid recollection to a large number of the members of our society. With each year, however, the number of those who bear in mind that impressive and inspiring personality must become fewer. To one who still retains it, the memory gives to the task of delivering this lecture a keen sense of responsibility, lest he should fail to strike the note of severe restrained regard for all that is highest in scientific effort which Bowman ever set. To rise to his level is beyond the power of more than one of those who each century may give his lecture, but the personal fear of inadequacy is lessened by the recollection that no one was ever more ready than he to see the effort where performance failed, to commend the trifling good, and to ignore that which, far more obtrusive, might reasonably warrant censure, a censure which, for merely intellectual failure, never, I think, came from him. I need this consciousness to-night, for I cannot follow his great example of absolute practical homage to fact, to fact observed with definite precision. Alike in the science of life in general,

and of one part of life in particular, normal and perverted, theory seemed to find no place in his work. No doubt it had its place and influence, in due position and degree, but it was subordinate and never obtruded. To-night I cannot escape from theory or from the compulsion of even obtruding it. True, times have changed. Speculation has grown, and hypothesis, as the scaffold for useful observation, has become necessary in a manner and to a degree of which the workers of half a century ago had perhaps no adequate conception.

In selecting the visual sensations that occur without external cause as the subject for this lecture, I hoped to be able to reduce to some order the numerous facts recorded in my case-books in connexion with epilepsy and migraine, and to do so with the help of that which has been discerned and described by others. But I have found among the facts some which seem to be so instructive in a special relation that I have felt compelled chiefly to limit myself to a small part of the subject. Even within this narrow range, instead of explaining, I find myself able merely to point out that which needs explanation, and this only in its salient outline, in the hope that others may be able to see more clearly from the standpoint to which they may attain, as steps are cut in the steep hill-side of fact. Thence a wider prospect and a true perspective may be obtained, as the winding path of daily work is ever bringing before the eye new views of that which has long been known and perhaps misknown. The facts with which I have to deal are those of everyday experience, and yet are only now and then presented to us in needful definiteness of form and precision of discernment. I can only hope to-night to indicate how the facts should be regarded. Unless some idea exists of what to look for, we shall see but little.

The difficulty of ascertaining the facts depends on their subjectivity. That which is to be discerned can be seen only through the vision of another. Moreover, this is the vision of the unreal; it is the sight of that which is not. Unreal as it is, to the subject it is, as a sensation, a profound reality that confuses the mind and may make even recollection painful. Hence the opportunities for ascertaining trustworthy facts are very rare, and when they come it is important that they should be made the most of. If that which I have to say to-night induces many others to seize some of the opportunities that abound, and to make known the facts they learn, I shall count my effort thoroughly successful.

As I have said, the visual sensations met with in the two diseases, epilepsy and migraine, are far too varied to be considered in detail in all their numerous forms. But they present one relation which transcends all others in interest, in difficulty, and in importance. This is the apparent relation of the sensations to the functions of the cerebral centres in which we must assume that they arise, and through which we must also assume conscious vision of external objects is achieved. In 1885 I put forward the opinion, which has been confirmed by all that I have since been able to perceive, that, in addition to the half-vision centre in the occipital lobe, demonstrated by Munk, the indications obtained by Ferrier are correct, and that there exists a higher visual centre in the region of the angular convolution, which immediately subserves the perception of visual impressions. As I then suggested, impressions seem to pass to this higher centre in each hemisphere from both half-vision centres in the occipital lobes, in such a way that in each higher centre both fields of vision are represented, but that of the opposite eye in greater degree; that the connexion between the two higher centres is very intimate; and that the function of the higher centre differs from the lower in two ways. First, it seems to present the mysterious feature that, while partial disease of the lower centre causes partial loss of the related half-field, which cannot be compensated, partial disease of the higher centre seems to lower the function of the whole in a way we cannot at present understand. Secondly, and perhaps associated with this, there is some capacity for the compensation of loss by the other hemisphere, especially in the lower animals. This may be one reason why the pathological evidence of this centre in man is so scanty, and another cause may be found in the fact that the centre is in the region of the blood-supply of two different arteries, and so is seldom entirely destroyed. The facts that suggest—indeed, I think, indicate—the existence of this centre in man I have repeatedly stated during the last ten years. In the strange hemianesthesia of hysteria we have evidence of arrested action of all the other higher special senses

centres in one hemisphere. We never meet in this association with the hemianopia that results from disease of the lower centre in the posterior extremity of the hemisphere. Instead we have the "crossed amblyopia," as it is termed; peripheral vision is lost in both eyes, central vision persists in a small area in the opposite eye, and in a larger area in the eye of the same side. No trace is found of any relation to the half-fields. But hysteria is a by-word, and all facts, however definite, with which the name can be connected are disregarded by physiologists. Yet the same affection of vision occurs in organic disease. I have given an illustration of it,¹ as a lasting symptom, in a case in which it was caused, with hemiplegia, by a sudden lesion, probably hæmorrhage, in one hemisphere. A similar loss has been met with when the angular region was found diseased.² When hemianopia is caused by disease of the cerebral hemisphere it is common for a like contraction of the remaining half-fields to reproduce the same change, greater on the opposite side.³ A careful scrutiny of pathological evidence makes it probable that in these cases the disease is in the white substance, interrupting the half-vision path and extending forward to the fibres beneath the higher centre or to its grey matter. These may seem meagre grounds for the assertion that here we have a higher visual centre, but they agree in a remarkable way with the experimental results obtained by Ferrier, and a large number of the facts of disease cannot otherwise be understood. A theory that explains is not necessarily true. But if a theory that affords an explanation which can be obtained in no other way, which theory has other, varied and quite independent evidence, it seems to me that we are justified in its assumption. I have to ask you to postulate these higher visual centres, for I can only describe the facts or at least suggest their significance by placing them in front of this hypothesis. I am compelled also to justify my request because these centres seem quite outside the limits of our present scientific physiology.

Note the necessary significance of "crossed amblyopia." With loss of the higher visual centre of the left hemisphere we have in the right eye vision only in a small central region; in the left eye sight remains in a larger central region. In each eye there is peripheral loss. The significance of this is that the vision that remains is subserved by the right higher centre acting alone. This subserves a large central region on the opposite side, a small central region on the same side, but, without the coöperation of the opposite centre, it cannot subservise peripheral vision in either eye. The facts are certain, and their meaning seems to me alike startling and unquestionable. It seems that in the central regions of the fields vision can be subserved by either hemisphere alone, in the peripheral parts by neither alone. It is as if the impulse from the periphery of each retina ultimately reached the higher centre of one side through the opposite visual centre, as if those from the peripheral region of each half-vision centre in the occipital lobe passed to the opposite hemisphere through the higher centre of the same side, and those for the central region passed directly from the half-vision centre to each higher centre. So that, for instance, the peripheral impressions of the right higher centre have to pass through the higher centre in the left eye, and the loss of this involves peripheral blindness on both sides. Whether this is so, or whether some reflected coöperation is essential, the facts show how extremely close is the functional relation of the two. In this higher visual centre we must assume the processes to occur on which the subjective visual sensations depend. From this conclusion I think there is no escape, and this may become apparent as we consider their features on this assumption. The more elaborate function of this centre may be connected with the instability which underlies these symptoms. They reveal not only how extremely close must be the connexion between the visual centres of the two hemispheres, but that, as regards some part of their functions, they must be regarded almost as one centre, as united in a manner more essential than that in which any other centres of the two hemispheres are conjoined. This is, indeed, not surprising when we consider how unique is the function of sight as subserved first by the two eyes, and secondly by the lower visual centres in which the half-fields are represented in so limited a manner. Only from the region of the fovea centralis do fibres pass to each occipital lobe. Only in a

small region around the fixing point, varying in size in different persons, but always too small to be revealed by the ordinary perimeter, is vision subserved by each lower centre. But the whole of each field is in some way related to each higher centre. The subjective visual sensations present the function of these higher centres from another point of view, from that of their activity, and not of their loss. The ground is one on which we have to tread with caution, in which the danger of fallacious inference is great, and yet that which is seen must contain in it evidence of facts which can be discerned in no other way.

THE VISUAL SPECTRA OF EPILEPSY.

The "warning" which occurs at the moment of the onset of an epileptic fit—the first effect on consciousness of the process of "discharge"—is often a visual sensation. This may be, or may not be, the first event. It may be preceded by some other sensory perception or it may be followed by some other, but it shows that the process of discharge occurs first or early in the visual centres. Such sensations are extremely varied, but they are, as a rule, constant in the same patient, and when they occur, consciousness is adequate to permit the memory to retain them. The simplest of these visual warnings are sudden flashes of light or colour, sparks or stars, often in rapid movement among themselves, apparently like the movement of water-beetles on a pond. Sometimes a large luminous object appears, which may move across the field, or seem to approach or to recede. There may be two such objects, rarely three, and they may be white or coloured. More elaborate sensations are figures of persons, faces, often distorted into grimaces; a figure may also move. Occasionally there is a vision of places or of some scene, even such as is quite beyond the possibility of past experience. Such elaborate sensations—"psycho-visual" as they may be termed—are often associated with definite mental states, which may be very curious. The warning in one patient was a definite picture of London in ruins and the river Thames emptied to receive the rubbish; that all the inhabitants had perished, and the patient stood alone in the scene of desolation. The associations of these visual sensations are noteworthy, but I must only mention the fact that the frequent associations are with other special sensations, especially with the sense of hearing, seldom with smell. The associated sensation is generally of the same degree of elaboration. A patient who sees figures will seem to hear words uttered by them, although the words are generally forgotten—an association which reminds us of the celebrated vision on which the fame of Lourdes arose. One curiously complex visual warning, experienced by the same patient through many years before every fit, I have described elsewhere, but it deserves mention. A sense of beating of the heart ascended the chest to the head and became audible as a pulsating sound; then two lights appeared before the eyes, which seemed to approach with jerks; they suddenly disappeared and were replaced by the figure of an old woman in a red cloak, who offered the patient something which had the smell of Tonquin beans, and then he always lost consciousness. The case is remarkable on account of the change of the sensation of simple pulsation to that of sound, and the association of the latter with a pulsating visual spectrum, the replacement of these by a highly complex spectrum, and the final termination with an olfactory sensation, probably elaborate. There is reason to think that the more pleasant subjective sensations of smell are more elaborate than the common disagreeable sensations. The jerky movement, definitely synchronous with the pulse, is not uncommon in such simple visual sensations, and seems to indicate that the process, in the disturbed centre of the brain, is modified by the mechanical influence of the arterial pulsations. I may point out also the interesting fact that the more elaborate sensation, the vision of the woman, followed the more simple one, the two lights. This sequence is more common than the opposite, although now and then an elaborate sensation is followed by one that is more simple. The sudden spontaneous activity, which we call "discharge" of the centre, may occur as a primary event, but it is often preceded by sudden arrest of function, by inhibition of the centre. It is one of many instances of the fact that the same functional derangement, in different degree, may cause cessation of action or increased action. In one case, suddenly all became dark, then there appeared a red light before the eyes, changing presently to green, and then consciousness was lost and the convulsion came on. In another, sight became dim and misty, then two round green lights appeared, compared to a penny at a distance of two feet,

¹ Manual of Diseases of the Nervous System, vol. II., second edition, Fig. 83 (first edition, Fig. 81).

² Ibid., Fig. 15 (first edition, Fig. 14).

³ Ibid., Fig. 82 (first edition, Fig. 80).

which moved from side to side. It is very common for the first darkness to be the background for bright stars. Much less frequently stars or flashes of light are followed by loss of sight and darkness—that is, discharge is followed by inhibition.

COLOURS.

The colours seen in these epileptic sensations are generally either green, red, blue, or yellow; a reddish yellow is especially frequent and seems to be very much the colour commonly assumed to be that of flame. Now and then emphasis is laid on the bright golden character of the yellow. The transition of red to green just mentioned I have met with in two or three other cases. It is interesting, on account of the complementary character of the two colours and the fact that the transition is central; but we are not yet in a position to discern anything regarding the nature of the colour process in the centres. The subject is of extreme interest in connexion with the problems of colour vision, to the physical relations of which so much attention has been lately given. I believe that ultimately the study of the central phenomena will throw light upon the subject, possibly of supreme importance, but the time is not yet come. The perception of colour in the visual sensations which precede epilepsy presents to us one feature which must detain us for a short time, because it is equally obtrusive in the visual sensations of migraine which I shall have presently to describe. It is the fact that the subjective colour sensations seem to extend to the extreme periphery of the field. They are as distinct and frequent in the peripheral region as in the central region. I could give you many illustrations, but one will suffice. Green is the colour which is said to have the smallest colour field, its perception being often described as confined to the central region. But to one patient, before each fit, there appeared the vision of a green colour over the whole lower half of the combined fields, extending from side to side and down to the lowest part, as was clearly shown by his spontaneous description that "it was just as if he were standing in a field of grass."

PERIPHERAL COLOUR VISION.

Different as the arrangement of function in the centres is from that in the eyes, there must be a perfect reproduction of the function of the retinal fields in the higher centres. Although it is in altered form, whatever vision the periphery of the retina subserves, the parts of the visual centres related to the periphery must subserve the same vision in the same way, similar in character and in degree. The fact that the subjective sensations may present every colour in the peripheral field—even green, to which the retina seems least sensitive—brings before us the question of peripheral colour vision. The facts I am about to state have been well known for nearly twenty years, since Chodrin⁴ worked at peripheral colour vision in regard to saturation. They were described by Landolt, but they are not very familiar, and they are curiously inconsistent with the statements commonly made. It is often said that the field in which red can be seen is the central region, the limit of which crosses the outer horizontal radius at 45°. This limit is even spoken of as "the boundary of the field for red." But it is only the area in which red can be perceived on an object one centimetre square. The same statement in regard to a still smaller region is made regarding green. But with larger area of colour it is found that all the colour fields differ in extent very little from the fields for white. On the temporal side in each field red can be seen up to 90°. Taking first the red field, it is found that it depends in size simply on the size of the coloured object. In the outer horizontal radius that for the half-centimetre square is, I find, at 35°, and for a quarter-centimetre square at 25°. If we pass beyond the one centimetre limit, which is commonly figured as that of the field for red, we find that a red area two centimetres square is seen at 60°, three at 70°, four at 78°, five at about 82°, while the area of six centimetres square is seen up to the extreme edge of the field. Upwards, downwards, and on the nasal side of the field, in which the range of vision is so much more limited, the areal limits are closer together, so that on the inner horizontal radius the three-centimetre limit is at 40° and the six-centimetre area of red can be seen at 50°—that is, at the edge of the field for white. Every field is thus practically concentric with the field for white. In

the case of blue and yellow still smaller areas suffice to permit the colour to be seen up to the edge of the field for white. Green alone seems to fall short of the edge of the white field by about 5°. I have spoken of areas of two or more centimetres square. But this is not accurate. At each distance from the centre at which the colour can be seen in an area of a certain dimension, the same in the radial direction and in the concentric direction, it can be seen equally well if the radial dimension is only two-thirds of the concentric dimension. As far as I have been able to ascertain, the peripheral colour vision is determined by area rather than by illumination, but I have found it difficult to get a sufficient saturation to bear strong illumination.

I have spoken of the mysterious way in which peripheral vision seems in the higher centres to be dependent on mutual cooperation, that in neither eye can peripheral vision occur unless the centres of both hemispheres are active, while in the central region there is vision in both eyes although only the higher centre in one hemisphere is active. This peculiar mutual influence of the centres is exemplified further by the colour fields. The field for every area is larger if both eyes are open. This seems natural so far as concerns the part of the two fields which overlap. But it is true also of the temporal part of each field in which the field is single. Binocular intensification extends into this part and extends into it in the same degree as in the part where the fields are double—for instance, in the outer (temporal) horizontal radius of the right field. In the single field red is seen in one centimetre square at 42°, in the double field at 60°, although the left field only extends as far as 56°. In a square of two centimetres red is seen in the single field at 62°, in the double field at 72°, and in a square of four centimetres in the single at 80°, while in the double field it can be perceived almost up to the edge at 90°. The fact that in the part of the fields in which each is single there is increased sensitiveness when both eyes act gives additional emphasis to the strange fact that, in this region, loss of one higher visual centre causes peripheral blindness. It shows how complete is the blending of function in the two centres. In this outer periphery vision is impossible unless both higher centres act, but where the rays of light fall on one retina only their effect is greater if the other eye is open—that is, if both centres are fully stimulated.

(To be continued.)

"RETURN" CASES OF SCARLET FEVER.

By A. K. CHALMERS, M.D. GLASG., D.P.H. CAMB.,
MEDICAL OFFICER OF HEALTH, GLASGOW.

A DEFINITION of the phrase as here used is scarcely necessary. It is intended simply to imply that when infection reappears in a household, after the return of one or more of the inmates from hospital, the two events are in some way connected, and the investigation of which this paper contains a summary was undertaken with the view of ascertaining, if possible, whether this connexion was capable of some definite explanation. It is usual to assume that this explanation is to be found either in the earlier patient or in his clothing; and while this, as a general statement, is sufficiently comprehensive, its application to the patient requires some consideration. In the first place, he may bear evidence of still being infectious; but the end of the period of infectivity is the termination of a pathological process, and there is some reason for believing that it may not coincide with the disappearance of the clinical signs which usually accompany its progress. In other words, the power to transmit infection would, in some instances, appear to attend a patient after recovery (?), and it shall be my endeavour afterwards to point out the conditions which tend to engender this power. Moreover, we have of late been made familiar with the phrase "recurring infectivity" as a clinical fact, of occasional occurrence at least, in cases of diphtheria, and the term would seem to be equally applicable to certain cases of scarlet fever. A third possible source of reinfection may lie in the household of the patient, but here it is to be remembered that the secondary cases are almost always resident at home, and unaffected, till the return of the hospital patient. It is true that articles of clothing which have been subjected to some process of disinfection, and have in consequence come to be regarded, is

⁴ Archiv für Ophthalmologie, Band xxiii. See also Landolt: a Manual of the Examination of the Eyes; and Swanzy: Diseases of the Eye, p. 19.

may be erroneously, as innocuous, may lie unused, under cover, until preparation is being made for the patient's return home, and one cannot exclude this as a possible explanation in some cases. A word may be permitted in this place regarding the manner of dealing with patients and their clothing in Glasgow. During removal to hospital a patient usually wears his ordinary clothing, but it may be supplemented by a blanket as a wrap. Whatever he wears on admission is taken charge of by the hospital authorities and dealt with as afterwards described. After removal, the house from which he comes is visited, and all the clothing worn while sickening, and the bed and bedding used, are disinfected by the "sanitary" as distinguished from the "hospital" staff. A very large number of the cases of scarlet fever occurring in Glasgow are removed to hospital for treatment. In 1894 this proportion reached 74 per cent. of the cases notified. At the present time the older fever hospital of Glasgow, in Parliamentary-road, receives by far the greater number of these patients, and during the period under review this hospital was used exclusively for patients suffering from this disease. A large number also are treated at Belvidere, while those whose residence is in the recently annexed areas of Hillhead and Maryhill are treated at the Joint Hospital, Knightswood. It should be here noted that while the system of "sanitary" disinfection and washing is uniform in all cases, the clothing worn by patients on admission to Knightswood Hospital is dealt with in a manner somewhat different from that followed at Belvidere and Parliamentary-road Hospitals, while patients dismissed from Belvidere are subjected to a carefully designed system of bathing, in a separately constructed "clearing house," which has no equivalent in either of the other two hospitals. My observations were begun towards the end of 1893 and were continued till the spring of the present year, and during this period over 3700 scarlet fever patients were dismissed recovered. The method adopted in the inquiry was to note as it occurred every case arising in a household subsequently to, or shortly before, the return of an earlier one from hospital. A record was taken of the number of days intervening between the date of return of the one and the sickening of the other, and the length of residence in hospital of the former case. This case was also examined for the existence of desquamation, nasal or aural discharge, excoriations, &c.—in general, anything which could be regarded in the light of a lesion—and when such was found the ward journals in the hospitals were subsequently examined for a history of the case. At the time of occurrence inquiry was also made regarding the intercourse which had been permitted between the cases, whether they slept in the same bed or room, whether they played together or had their meals in common, and generally also regarding those demonstrations of affection which naturally accompany the return of any member of a household who has been absent for some time. In regard to clothing the inquiry was directed to ascertain what had been worn on going to hospital and what on returning; and how such clothing as had been worn at the time of sickening, but not on removal to hospital, had been disinfected, and whether it had, during the interval between disinfection and the return of the patient, been kept hanging loosely about the house, or under cover, as in a box or drawer. As might be expected, however, from the natural tendency of many people to discount the presence of infection in any articles of clothing which might be injured by disinfection, this line of inquiry was approached with the conviction that if the wearing of good clothing was coincident with the date of sickening—as might well happen when that occurred on a Sunday or a holiday—error would now and again arise from suppression of the fact that such clothing had been exposed to infection. The careful preservation of such articles in some receptacle against the time when their owner is to be discharged from hospital must be regarded, I think, as a likely explanation of such attacks, at least, as shortly precede the return home of an earlier case. Inquiry was also made as to the existence of any other extraneous source of infection, such as, for example, a case in a neighbouring house. My list comprises 118 cases collected as described. In this list there are, however, 19 which I shall afterwards deal with as "extra" cases, because several are not "hospital" return cases, although having points of interest bearing on the present inquiry, and some are duplicate cases occurring in the same house a day or so after a first sickening. These latter must of course be excluded in calculating the proportion which the re-lit centres of infection bear to the dismissals from hospital, so that the per cent. of

"return" cases to dismissals becomes rather a statement of the number of houses in which infection reappeared in association with those dismissals. In calculating this per cent. I have taken the figures for 1894 because of the greater precision which this limitation affords. During that year 2593 persons were dismissed "well" from the three hospitals above mentioned, and reinfection appeared subsequently in 70 of the houses to which these patients returned, or in 2.6 per 100 dismissals. Of these dismissals 1535 were from Parliamentary-road Hospital, 901 from Belvidere Hospital, and 157 from Knightswood Hospital; and infection reappeared in 37 of the houses receiving patients from Parliamentary-road Hospital, in 22 houses receiving patients from Belvidere Hospital, and in 11 houses receiving patients from Knightswood Hospital. Otherwise stated, infection reappeared in 2.41 per 100 dismissals from Parliamentary-road Hospital, in 2.44 per 100 dismissals from Belvidere Hospital, and in 7.0 per 100 dismissals from Knightswood Hospital. Belvidere and Parliamentary-road Hospitals may therefore be taken to have practically the same proportion of reinfections associated with their dismissals, and in view of the difference which obtains in these hospitals in the method of dealing with the patient immediately prior to dismissal this correspondence is striking. Wherein this difference lies will be best apprehended if I here introduce a description of the process which Dr. Johnston, physician-superintendent of Belvidere and Parliamentary-road Hospitals, has been good enough to write for me. The description covers also the method of dealing with the clothing worn by patients on admission and dismissal. Dr. Johnston says:—

"1. *Patient.*—(a) The minimum period of residence for scarlatinal convalescents is fixed at eight weeks. Only between Nov. 7th, 1892, and Jan. 4th, 1893, was it reduced, owing to unusual pressure, to six weeks. (b) The criteria for dismissal are that patients are in good general health. All the cutis must have separated and the surface of the body be quite intact. There must be absence of discharge from ears or mucous surfaces, and the urine must be clear. Cases have, sometimes to be dismissed with chronic ear discharge or albuminuria, but never are so dismissed under three months. (c) On dismissal patient is taken to a special series of rooms (discharging-rooms). He enters and strips in the first, has a bath with carbolic soap in the second, passes along to the third, where he dresses in clean, non-infected clothes, and thence he is shown outside the gates of the hospital.

"2. *Clothing.*—The clothing worn on admission by a patient is removed and sent to a special laundry within the hospital grounds, where it is thoroughly cleansed by washing and packed away in a bag. These bags are placed on racks in a large, airy store-room, specially built and set apart for the purpose, and carefully preserved from contamination. Immediately before patient's dismissal they are sent to the sanitary washhouse, where they are exposed to superheated steam in a 'Washington Lyon' apparatus. Clothing brought to the hospital to be worn on dismissal is detained either in the 'third' room of the discharging series or in the store-room.

"*Note.*—A nurse from the patient's ward accompanies him to the discharging-rooms and superintends the disinfecting process of bathing &c. The nurse puts on a clean cotton wrapper over her uniform for the occasion."

The foregoing description applies to Belvidere Hospital.

"At Parliamentary-road Hospital there are no discharging-rooms, and the ward bath-rooms (which are to some extent liable to harbour infection) have to be used. In all other respects the practice, however, is the same as at Belvidere."

With regard to the methods followed at Knightswood Hospital, Dr. Iain Clerk, the physician-superintendent, has also favoured me with the following description:—

"1. *Patient.*—(a) The average residence last year was fifty-two days. No case is dismissed under seven weeks, dating from the first day of illness. The criteria for dismissal are (b) completion of desquamation, special attention being directed to the feet, hands, and hairy (!) scalp. An examination of patient is made on the day before that on which he is to be dismissed. Patients with ear or nose discharges are not dismissed until recovered. (c) Patient is bathed in a bath connected with the ward before being dressed for dismissal, and is dressed in the nurses' room—both bath and nurses room being entered from the corridor leading to the ward.

"2. *Clothing.*—Whatever is worn on admission is fumigated with sulphur, washed, and kept in a store (at the offices) until the day of dismissal. Clothing sent in preparatory to

dismissal is simply stored. It is often brought on the morning of dismissal day.

† *Note.*—An occasional case where chronic ear discharge was present before the attack of scarlet fever may have been dismissed 'improved,' but not cured. The patients are dressed by the ward nurses while wearing their ordinary ward uniform."

In the following table the secondary sickness is stated as occurring on the second, third tenth, eleventh days after the return of an earlier case. Deducting the 19 cases formerly mentioned this interval is stated for the remaining 99.

* In one case a downstairs neighbour had a case of scarlet fever at home.

† One boy had played with a more recent dismissal from hospital (seven days) who lived at hand.

‡ (Fifteenth day.) In one of these cases—not associated with lesion—the secondary case was sent from home for eight days at time of return of earlier one. The clothing was kept in a box.

§ Earlier cases here on leaving hospital went to the country for thirteen days. All new clothes.

Sixty-one cases are here shown to have sickened within one week of the return of an earlier case from hospital, and 8 in the third week thereafter, but it will be observed in the note to the table that one attack beginning on the fifteenth and another on the nineteenth day after dismissal really occurred on the seventh and sixth days respectively after exposure, and if we transfer these to the first week we have 93 per cent. of the reinfections occurring within a fortnight after dismissal. It may be protested that to credit a dismissal from hospital with a sickening occurring in the third week thereafter is inconsistent with the knowledge which we have, derived from other sources, of the incubation period of scarlet fever, and that to include one sickening after an interval of twenty-eight days is indefensible. In the investigation, however, I practically took every case coming to my knowledge where infection reappeared in a household, and when it became evident that the recurrence of lesions subsequent to dismissal from hospital had at least a time association with cases sickening as late as the fifteenth and sixteenth days, it was difficult to know when absolutely to exclude others where the connexion was not so apparent. To such cases where lesions reappear I am disposed to think we should restrict the term "recurring infectivity," for there are others where no lesion is apparent, but where there is ample ground for the conjecture that the power of transmitting infection is retained after the lesions have ceased.

By far the most obvious connexion between the primary and secondary cases has reference to the presence of desquamation or other physical and easily recognisable lesion on the persons of those discharged from hospital. I do not mean cases where, for well-defined reasons, patients are deliberately dismissed from hospital during the period of desquamation or the currency of any of those lesions which are admittedly a sequel to the disease, but where the opposite policy prevails and where every precaution is taken that no patient shall be dismissed until the last patch of skin has repaired and the patient otherwise has returned to health. This, modified by the existence of a chronic lesion alone, was the policy which controlled the discharge from hospital of the cases under examination. It is interesting, therefore, to observe that in connexion with the reappearance of the disease in 19 households there was lesion of some kind present on the first patient, not, as we shall see, at the time

of dismissal, but at the time when the secondary case sickened. There is only one exception to this in the 19 cases here referred to. The form of lesion present may be classified as follows: in 8 of the patients there was desquamation, and a like number presented sores (excoriations, eczematous patches, &c.) on the lips, ears, or head; in 5 there was a discharge from the ear; 2 had a discharge from the nose; and 1 had sore-throat. It is of importance to examine these cases further with reference to the course followed by the disease during their residence in hospital, and I have accordingly gone over these records in the ward journals, and in the following table (Table 2) I have introduced such notes therefrom as tend to throw any light on the lesions which were present after their return home. In the table the cases are arranged according to the interval which elapsed between the dismissal of the primary and sickening of the secondary case. Thirteen were from Belvidere and 5 from Parliamentary-road Hospitals.

Table II. is largely self-explanatory, and the significance of the morbid conditions found present when the secondary cases arose depends, as I have said, on the fact that, with the exception noted in the table, these were not present at the medical examination prior to dismissal from hospital. It is easy to understand the recurrence of a discharge from the ear when it has once been invaded by suppurative inflammation; but the suggestion in this table distinctly is that it may also be associated with a recurrence of the specific infectivity which at first gave it origin. Again, evidence of desquamation on some part of the body was present in nearly half of the number in which lesion was discovered, and it is impossible to regard its occurrence at the time of the secondary sickening only in the light of a coincidence. Before disputing the connexion, indeed, we should first of all endeavour to realise the effect of the altered conditions which attend a patient on dismissal from hospital. In the Glasgow hospitals there is ample scope for the activity of children who are sufficiently advanced in convalescence to indulge in outdoor play. But otherwise they live under a strict discipline; their meals are regulated, absolute cleanliness is a necessity, and strict attention is paid to the performance of the physiological functions. It is idle to speculate whether, had the cases at present under consideration remained under this régime, the desquamation would have occurred; I am inclined to think it would not. This much, however, is tolerably certain: that on return to their homes the method of their lives is changed—undue strain is thrown on one or other of the assimilative or excretory functions, the physiological balance is for the time being destroyed, and an error in dietary, resulting in disordered digestion, may find expression in the skin relapsing into a habit which it had but lately given over. Nineteen of the 99 cases under discussion presented some such lesion as is here described—that is, 19 per cent., or nearly one-fifth of the whole number associated with secondary cases, may be regarded as examples of "recurring infectivity."

Apart from the correspondence which exists between the proportion which the total yearly number of reimplemented cases bears to the dismissals both from Belvidere and Parliamentary-road Hospitals, suggestive differences appear when the monthly incidence of these cases is considered. In Table III. are given, in monthly periods—(1) the average daily number under treatment; (2) the total dismissals; (3) the number of these associated with cases of reimplemented infection; and (4) the percentage which these last bear to the dismissals. The first feature in the table attracting attention is the constancy with which the dismissals from Parliamentary-road Hospital are associated with return cases, and the break in this continuity from May till August in connexion with those dismissed from Belvidere Hospital. To borrow a term, "return" cases from Parliamentary-road Hospital dismissals assume a certain "chronicity," while those from Belvidere Hospital are "intermittent." Along with this it will also be noticed that the average monthly numbers under treatment at Parliamentary-road Hospital are maintained with a fair amount of constancy, while the Belvidere Hospital numbers are largely diminished during the summer months, and one asks whether there is more than an accidental association between the two. Obviously, it is to be remembered that continued strain either on the accommodation or on the management of a ward will tend to produce impaired efficiency of the work, and that "return" cases associated with dismissals under these circumstances may possibly be the result of conditions which have been overlooked. This would lead us, however, to expect that the largest proportion of

return cases, and especially those displaying "lesions," would attend dismissals when this strain is most acute, as at the beginning of an epidemic prevalence of the disease. It would, therefore, usually be in the fall of the year that this proportion should be increased, and yet a comparison of all the monthly figures between September and December shows that this is not the case. An excellent illustration, indeed, of this autumnal pressure is afforded by the condition of Parliamentary-road Hospital in the early part of October last year. On the 10th of that month in the twelve wards then in use, and which on a 1250 cubic feet allowance for each patient had only accommodation for 266 patients, there were 316—that is, there was at this date undoubted and excessive strain both on the management and on the bed space; and yet October is the only month in which no return case is recorded against this hospital, while in November these

reached only 1.3 per cent., and in December there was only 1 return case in 163 dismissals. In Belvidere Hospital also, as the table shows, the rapid increase in the numbers under treatment in the later months of the year is not accompanied by an increase in the proportion of return cases. Nor is there any evidence apparent of an increased tendency in "return" cases to associate themselves unduly with the season of large dismissals, and the evidence is altogether adverse to the view that the return cases result either from relaxed stringency in dismissal or from an overcrowded condition of the wards themselves when this is of a temporary character. It will strike one, however, on examining the table that the increase in the numbers under treatment in Parliamentary-road Hospital during the months September to December is not comparable with what took place in Belvidere Hospital during the same period. I have

already stated that during 1894 Parliamentary-road Hospital was used exclusively for the treatment of scarlet fever, and this contrast but serves to show that the available accommodation therein was largely taken advantage of throughout the year, and that when the autumnal rise took place accommodation for it had chiefly to be found elsewhere. In Parliamentary-road Hospital, on a computation of 2000 cubic feet per bed, there is accommodation for 198 beds, while if only 1500 cubic feet per bed are allowed 267 can be accommodated. It is customary to regard children under ten years of age as requiring only one-half the cubic space of adults, but if we allow 1250 cubic feet per bed there is accommodation for 322. In the first nine months of the year only twelve wards were in use in Parliamentary-road Hospital, and on a 1500 cubic feet allowance per bed the accommodation in these is 221. The average daily number under treatment, it will be seen, was frequently much in excess of this and rarely fell much below it. There is, however, a manifest risk in pressing this comparison on averages alone, because mere unequal distribution of patients among the wards might, it can be readily understood, create overcrowding in a ward here and there, while the total number in hospital might be much under the accommodation, and the comparatively small number of return cases at our disposal precludes any effort to follow backwards each dismissal into relationship with the numbers who were treated simultaneously with him in individual wards. In their present form, however, these numbers, I believe, suggest that when wards are continuously worked very nearly up to their maximum accommodation, more especially when this accommodation is based on a low estimate of the cubic space per head required for children, there is a tendency in the dismissals to become associated with return cases, and that the cause thereof would seem to lie in the air of the ward becoming surcharged with the products of scarlatinal elimination. Other results of this we are already, indeed, familiar with. Dr. Sweeting some years ago showed that the aggregation of acute cases in wards led to increased frequency of albuminuria; and there is, moreover, the well-recognised risk that small-pox will attack the population in the immediate neighbourhood of a hospital when the wards are worked at their maximum accommodation and the air has acquired a property which is well expressed by the phrase "explosive intensity." In the present circumstances it would appear that, apart from the possible return of readily recognisable conditions such as desquamation &c. after dismissal, there is a constitutional effect produced which renders the discharged convalescent a danger to susceptible persons who may be brought into close contact with him. That this results from saturation of the system is, I think, clear; but whether it is due simply to delayed elimination, or to the constant breathing of a saturated atmosphere by the convalescent, is matter for conjecture. In the latter case one would expect that nurses would occasionally be the means of carrying infection outside a hospital, and yet evidence on this point, save where clothing has been the medium of conveyance, is wanting. From the analogy of diphtheria it might be expected that an unrecognised retention of infection may take place in the nares or fauces, or even further down the respiratory tract, and proceeding on this assumption, some effort was made to have the naso-pharyngeal cavities of convalescents douched with a boracic acid lotion on dismissal. These observations were, however, too incomplete for any deduction, and, moreover, the occasional recurrence of desquamation apparently points to a much more general retention in the system than any such localisation would explain.

Sleeping accommodation.—It is from this aspect, therefore, that a patient dismissed from a scarlet fever ward may carry with him elements of risk to the susceptible, that an investigation of all such acts as bring them into contact becomes important. I have previously stated that part of the investigation had in view the discovery of the sleeping accommodation both of the dismissed cases and of the cases sickening subsequent to their return from hospital, as well as of any other incident in domestic intercourse which might bring them into contact. The record of the sleeping accommodation shows that of the 61 sickening in the first week 17 occupied the same bed, 21 slept in the same room, and 23 slept in different rooms. Of those sickening in the second week (29 in number) 10 slept in the same bed, 7 in the same room, and 12 in another; while in the third week 3 occupied the same bed, 2 the same room,

and 3 slept in separate rooms. In almost every instance, also, it is noted that the patients either played or had their meals together, and there are few in which contact of one sort or other could not be definitely ascertained.

Clothing.—For reasons already stated this analysis is unsatisfactory, and there is the additional difficulty which arises from the almost hopeless confusion of new with old clothing, as most children leave hospital in clothing which is partly new and partly old. When a patient goes to hospital fully clothed, as is frequently the case, his clothing after disinfection may be sufficient for him when leaving. On the other hand, new clothing or, as most often happens, some new and some old articles of clothing are sent by the friends in preparation for the dismissal. Of the 99 patients 68 left hospital in clothing wholly or partly new—that is, 31 had no new clothing whatever in which to return home; 51 returned wholly or partly clothed with the articles worn by them on admission and retained in hospital; while 48 wore articles which had been kept at home after disinfection by the sanitary department. To these 48 cases most interest attaches, and I find that in 47 this disinfection was carried out by removal of all or part of the clothing to the sanitary wash-house, while in 11 cases articles were also fumigated at home—that is, in only one house had there been nothing disinfected at the sanitary washhouse. As to the manner in which those articles kept at home had been so kept, and chiefly having in view the place of their retention, as in boxes or drawers, or hanging on nails behind doors or otherwise, I find that in 17 cases the clothing was hanging so exposed, while in 29 it was under cover. Apart from the greater proportion of cases associated with clothing kept under cover, there is nothing in the analysis of the clothing otherwise which helps to explain the occurrence of the secondary cases.

EXTRA CASES.

Several of the additional cases on my list fall into the two following groups, which are of some interest.

Group 1.—This group illustrates, I believe, reinfection resulting from overlooked or improperly disinfected clothing. In one family 3 children sickened on the following dates: March 20th and 23rd, and April 2nd. On March 23rd the first two that sickened went to hospital, and the third case, a boy, went to stay with friends, returning home on March 29th. He sickened four days thereafter. While with his friends he wore a new suit of clothing, but on returning to his own home on the 29th he had on clothing which he had been wearing while playing with the others while they were sickening and which had been fumigated at home, the underclothing being washed. In another instance a boy aged two years sickened on the day preceding the return of his brother from hospital. Some old clothes had been looked out in anticipation of the first boy's return home. In yet another case a boy aged two years sickened on the day of his brother's return. The clothing here had been kept at home, some in a drawer, other articles hanging loosely. The last instance is that of a boy who sickened a few hours before the return of his brother.

Group 2.—This group shows that the risk to children residing in a house in which scarlet fever is being treated is largely intensified just at the time when disinfection is being carried out. This is probably sometimes owing to the mechanical displacement of dust while the process of cleaning is going on. In one family the first child to sicken was nursed at home, and the house was disinfected on April 26th. On April 29th one child sickened, followed by two others on May 2nd. These children had been at home during the whole time of the illness of the first case. In another instance the first case was treated at home. After recovery the house and clothing were disinfected, on Jan. 29th. The patient and another boy slept together the same night, and this boy sickened on Feb. 3rd. In a family in which an earlier case was treated at home the house was disinfected on March 20th. One boy, who had been all the time in the house, and another who returned on the 24th from a friend's house sickened on the 26th.

CONCLUSIONS.

1. *The doubtful value of soap and water.*—We have already seen that in Belvidere Hospital the bath on dismissal is taken in a completely detached building and that the toilette is completed in a room on the further side of the bath from the undressing one. In Parliamentary-road Hospital this is done in the ward bathroom. Notwithstanding this, the percentage of return cases is fractionally

greater in connexion with dismissals from Belvidere Hospital than with those from Parliamentary-road Hospital. Theoretically the Belvidere Hospital results should be much better than those in the other hospital, but in the period under observation it has not been so, and, although wider observation might correct the impression, the assumed advantage of the separate system of bathing is not at all apparent in the present investigation; indeed, it raises a doubt whether the *nimbus* of infection which attends a convalescent scarlet fever patient, even beyond the gates of the hospital, is capable of removal by soap and water at all.

2. *Reappearance of desquamation and other lesions.*—In a few cases certain lesions—chiefly desquamation and discharges from the ear and nose—will recur. In the present investigation evidence thereof was present in 19 per cent. of the dismissals associated with return cases. This recurrence would appear to be dependent on the altered conditions which surround patients on their dismissal from hospital.

3. *Influence of overcrowded wards.*—In the majority of dismissals associated with return cases there is no visible lesion, and the endeavour to impugn overlooked or insufficiently disinfected clothing is rarely satisfactory. But there is a tendency in return cases to associate themselves with dismissals from wards where the beds are kept well occupied, and as a very large proportion of scarlet fever patients are children there is some reason to question the accuracy of our present estimate of the smaller cubic space required for them. This could only be finally established by concerted observation of individual wards extending over a long period. From a collective measurement of the ward space the average monthly numbers under treatment in Parliamentary-road Hospital for nine months had an allowance per head ranging between 1250 and 1500 cubic feet, and it is doubtful if at any time the numbers under treatment were within the estimated accommodation at 2000 cubic feet per head. Continued occupancy on a restricted estimate of the requirements, rather than acute but temporary overcrowding, would appear to tend to produce the condition from which many return cases arise.

4. *Interval after dismissal within which the return cases occur.*—Ninety-three per cent. of these are shown to have occurred within fourteen days, and in every case there was community of life either in sleeping or while at meals or play. As a practical instruction to parents the lesson is plain. Every effort should be made to prevent commingling of the recently recovered with healthy children. The restriction placed on their sleeping together should be absolute. Where, moreover, children are treated at home, and the isolation has been successful, special care should be taken of other children during the period of disinfection. All this would seem to point broadly to the necessity for convalescent homes being established as a resting place between the hospital and the patient's home, so that, if the expression be permitted, the system might be washed by the constant breathing of untainted air. But here, again, there would finally arise a scarlet fever laden atmosphere, and if my impression of the effect of this is correct, we shall avoid the consequences rather by regarding the 2000 cubic feet per patient, or its equivalent in air-supply, as an irreducible minimum irrespective of the age of the patient. I have purposely omitted to compare the higher percentage of return cases associated with dismissals from Knightswood Hospital because the numbers are small, but it will not have escaped notice that patients' clothing is not here exposed to steam disinfection, as in the other hospitals.

Sanitary Chambers, Glasgow.

CASES OF LIVER AND GALL-DUCT SURGERY.

By JOHN D. MALCOLM, M.B., C.M., F.R.C.S. EDIN.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

(Continued from p. 1567.)

CASE 5. *Operation for hydatids in a child five and a half years old.*—This case was that of a child five and a half years of age, whose father's father had died from cancer and whose mother's sister had died from an internal tumour after middle life. The child was one of six—two older and three younger, all being very healthy and strong. A lump in the upper part of the patient's abdomen had been noticed for two

years. It was gradually increasing in size and seemed to be the cause of attacks of pain by which the child was occasionally seized. She was under the care of Mr. Soffe of Harling, in Norfolk, and Dr. Benjafield of Lower Edmonton had seen her with him. As the diagnosis was obscure, Dr. Benjafield brought the patient to consult Mr. Knowsley Thornton, who expressed the opinion that the swelling was a hydatid tumour, and it was arranged that I should operate. When I saw the child there was a tense rounded prominence on the front of the liver, measuring about two inches in diameter, and its central part being behind the upper portion of the right rectus muscle. It exhibited a distinct hydatid thrill on percussion. The outline of the liver dulness was not altered, but it was rather lower than is usual even in a child. The patient was the daughter of a farmer who kept and bred dogs, and this child was particularly fond of them, and was especially pleased when playing with the puppies, which are often infested with tapeworms. The child was brought to lodgings near my house, and on April 21st, 1892, assisted by Dr. Benjafield, I cut down upon the swelling, opened a hydatid about the size of an orange, and removed the lining capsule and the daughter cysts. I found that there was a slightly smaller cyst above and close to the first. This was opened and cleaned out through the cavity of the first. On examining the parts around I found a large number of small growths scattered apparently irregularly over the peritoneum. They were about the size of hazel nuts, and I supposed them to be hydatid cysts. Three of them were very slightly attached to the omentum and were removed. I did not cut into these growths for some months, and when I did I found that they were lymphatic glands. They were very large glands, even for a child, and I was then under the impression that lymphatic glands were not to be found in the omentum. I was, of course, prepared to find hydatid cysts in the sub-peritoneal connective tissue by the conditions I had observed in the case last related. The opening in the liver was secured to the abdominal incision and the sacs were drained by rubber tubing. During convalescence there was little trouble except from the fractiousness of a somewhat spoilt child. The temperature, taken in the groin, and the pulse rose respectively to 102.6° F. and 120 on the second day after the operation. By the end of a week they were down to 97.6° and 96. On the ninth day the temperature rose to 103.2° and the pulse to 120 without any cause that I could discover. The drainage-tubes had been removed, washed, and reinserted some days before, and the bowels had also been moved freely before this time. By the tenth morning the temperature was again down to 97.6°, the pulse to 96, and a temperature of 99° was the highest recorded after this until the child had gone home. The drainage-tubes were gradually shortened, and the patient left London five weeks after the operation, on May 25th. The tube was then about an inch long, and it was finally removed a week later, but the wound did not completely heal till the beginning of August. By this time the child had grown much stronger and stouter, but a short time after the wound healed she complained of much pain in the abdomen and of feeling sick. There was some swelling round the scar, and the abdomen was very hard, but there was little if any tympanites. The patient vomited at times, was disinclined for food and lost flesh, and her temperature rose as high as 102°. Dr. Benjafield saw her with Mr. Soffe, and opium and belladonna were administered, with hot applications locally. On Sept. 13th Dr. Benjafield reported a steady fall of temperature, relief of pain, and improvement of appetite. The attack passed off without further trouble, the patient soon grew fat and strong again, and she has had no trouble since. Later, two years and ten months after the operation, the child's mother wrote that she is "perfectly well and strong, and never has an ache or a pain." The cause of the attack of fever and pain four months after the operation in this case is obscure. I am inclined to think that as the child grew stronger the adhesions of the liver to the abdominal wall became gradually weaker by the constant movements of the parts on each other, and that the liver finally broke loose by a rapid rupture of the remaining adhesions. If this explanation is correct the child's liver is probably as free now as if there had been no operation.

CASE 6. *Operation for 789 stones in the gall-bladder.*—The first patient on whom I operated for gall-stones had consulted Dr. Stephen Mackenzie and Mr. Knowsley Thornton,

both of whom had diagnosed the presence of calculi and had recommended operative treatment. The patient was admitted to the Samaritan Free Hospital under my care on June 20th, 1892. She was a healthy, strong woman fifty-eight years of age and had suffered from frequently recurring attacks of pain in the region of the gall-bladder for three years. These attacks began with a very severe one, lasting a week, but not accompanied by sickness or jaundice. A year later, in July, 1890, there was another severe attack, with sickness, jaundice, and clay-coloured stools. The condition of the urine was not noted. This attack ceased suddenly, and after it two small calculi were passed by stool. The patient was free from pain for some months, and then had frequent slight attacks with varying intervals. In February, 1892, she had intense pain for a day and a night, ending, as most of the attacks had done, suddenly. After this the patient never felt well, having always a sense of discomfort and often a dull aching in the hepatic region. Jaundice had only been present on one occasion. There was nothing that seemed to bear on the patient's condition in her family history. She came of a healthy stock, and except for the conditions described and for constipation her own health was excellent. On examination by inspection and by percussion there was nothing abnormal in the abdomen, and by palpation I could not detect any enlargement of the gall-bladder, but in its situation there was some tenderness which varied from time to time, being sometimes diffused over a considerable area, and sometimes hardly present at all. There was always one tender spot on deep palpation, and I judged that this was about the situation of the common bile-duct or cystic duct. The patient wished to go to visit a son in a part of Canada where she would be out of the way of medical assistance, and this was taken into consideration in advising her to submit to operation. On July 12th, 1892, I cut down upon the gall-bladder and found it enlarged but flaccid. On grasping it between my fingers I could bring its opposite sides together, and here and there I could feel and catch hold of a small stone. The impression I got was that there were very few calculi, but when I had drawn off about an ounce of bile by means of an aspirator I found that there was a very large number of stones in the bladder. I made an incision in the fundus and cleared out the contents of the gall-bladder by means of forceps, a lithotomy scoop, and sponges. The opening in the gall-bladder was fixed by silk sutures to the abdominal wound so as to make a fistula. The rest of the incision was secured in the usual way, and the gall-bladder was drained by means of a rubber tube. Of course, great care was taken to prevent fouling of the peritoneum. There were 789 stones collected and counted. The largest was broken. It measured about three-quarters of an inch in its longest diameter, and was of irregularly rounded shape. The greater part of the stones were smaller than a split pea, many were smaller than hemp seeds, and the total bulk in fluid measure when they were dried and well shaken down was a little over an ounce. Besides those counted there were innumerable very small calculi which came freely through the aspirating needle and were seen as mere specks in the bile. Convalescence was very smooth. The temperature rose to 101° F. before midnight of the day of operation, and it was never above 100° in the vagina after the second day. The highest pulse was 80. There was at first a copious discharge of bile, but after a fortnight it diminished greatly. The tube was removed on the twenty-fifth day. There was very little discharge after this, and the patient went home a month after the operation; but it was about three weeks longer before the wound finally healed. The patient gradually regained her strength. I last saw her at the end of August, 1893, thirteen months after the operation. She was then about to start for Canada, having been detained by the illness and death of a son, which had entailed on her much work and worry, but there had been no recurrence of gall-stone symptoms.

CASE 7. Operation for gall-stones.—The next case was that of one of Mr. Alban Doran's patients, but he has kindly permitted me to record it here, as I had charge of the case and performed an operation on the patient during his temporary absence. "A woman aged forty-two years, a widow, came under my care at the Samaritan Free Hospital in October, 1893. She was a laundress, tall and once strong. On Aug. 4th, 1893, she lifted an unusually heavy basket of linen. Three days later she was seized with abdominal pains, vomiting, and sweating. There was no

jaundice. After resting three weeks in bed she went to work. Early in September another attack of pain came on, without sickness. Dr. Nias and Mr. Arathoon attended her at the Marylebone General Dispensary. She recovered from the pain, and I saw her on Oct. 10th. There was a swelling in the region of the gall-bladder. On Oct. 14th a severe attack of pain occurred. On the 19th the patient was admitted. An attack occurred on Oct. 22nd. The swelling grew larger, and the skin over it became reddened. In a few days the pain went away, but the redness increased and the integuments were cedematous. I suspected obstruction of the gall-ducts. Mr. Knowsley Thornton, who kindly examined the patient, was of a similar opinion, though he thought that possibly the swelling might be an inflamed hydatid cyst. On Nov. 7th I, assisted by Mr. Malcolm, made an exploratory incision along the outer border of the right rectus over the middle of the swelling. I found under the muscular layers an irregular cavity containing pus, clots, and shreds of broken-down tissue. There was hardness behind the cavity. A pocket trocar and cannula was thrust into the hard surface, but nothing oozed out nor did the trocar touch anything that felt like a calculus. I then believed that the cavity might represent an abscess in the abdominal walls, developed early in August after a bruise from a heavy clothes-basket. I washed out the cavity with iodine water and drained it. I did so, believing that if the disease was simple abscess it would thus be cured; if it were more than abscess further operation could be more safely undertaken when the cavity was rendered aseptic. For a few days the patient seemed to be better. I then, on account of severe indisposition, left her in Mr. Malcolm's charge." At this time the patient was not jaundiced. The abscess gradually contracted until only a sinus remained, but this showed no tendency to heal, and a thin mucous fluid oozed up from the bottom of the wound. On examining the parts towards the end of November I discovered that I could pass a probe through the wound into the gall-bladder, which was evidently full of stones. It was arranged that I should remove them, and on Dec. 2nd I enlarged the opening upwards and extracted a number of stones, but when I had removed all I could find, no bile escaped. It was evident that if I did nothing more the secretion from the gall-bladder would prevent the closing of the fistula, and but little, if any, good would result from the operation. I therefore made a free incision upwards and downwards about three and a half inches long, opening the peritoneum, separating the adhesions of the bladder to the abdominal wall, and cutting out the track of the fistula. It was still impossible to handle the gall-bladder because the omentum and transverse colon were adherent to it and to the lower surface of the liver. These adhesions were also separated until I could manipulate the gall-bladder freely. By means of the fingers outside the bladder, and a finger or instrument in it, I found and extracted some more stones, making 134 in all. The smallest of these was about a quarter of an inch in its longest diameter; most of them were rather larger than this, and three or four measured half an inch across; one large one was broken. Still no bile escaped, and although I explored thoroughly all the under surface of the liver and the parts along the course of the ducts I could not find any other stones. I was, therefore, reluctantly compelled to close the wound, the gall-bladder being fixed and drained as in the previous case. In this instance I also inserted a glass drainage-tube into the right loin pouch of the peritoneal cavity to remove quickly any discharge from the divided adhesions. Very little serum escaped through this tube, and it was removed forty hours after the operation. The highest temperature after operation was 101° F. on the first day, the pulse did not rise above 100, and the fever quickly subsided. There was very little discharge from the gall-bladder at first, but after the third day it increased and was distinctly tinged with bile. On the sixth day some fragments of stone escaped, and on the ninth day the dressings were soaked with bile. On the tenth day another piece of stone, nearly as large as a pea, was found in one of the drainage-tubes, but now no bile escaped; and after this there was never more than a tinge of bile occasionally in the discharge, which was again scanty. Mr. Doran resumed the charge of the case on Dec. 19th, and "the patient was discharged in the middle of January, 1894, with a fistula. She called on me

¹ Mr. Doran has kindly written the portion in inverted commas for me.

occasionally. She was readmitted in May. As the fistula had not closed and as a hard body could be felt by the probe and the attacks of pain continued I operated on May 25th, assisted by Mr. Malcolm. First I passed a long probe up the fistula. The patient was well under chloroform, yet I could not feel anything like a calculus, though two days before I had made the probe touch a body which felt precisely like a gall-stone. I opened the upper part of the old cicatrix and cut through the fistula in the parietes. After cautious probing I found that the gall-bladder could be entered. By means of a probe-pointed hernia knife the fistulous opening was enlarged. The finger could be then passed into the fundus of the gall-bladder, which was found to be just below the level of the fistula. Therefore I cut upwards to the extent of an inch and a half. Then I passed in my right forefinger and felt a small stone. By manipulation it was extracted. Then I passed a child's lithotomy sound and found the cystic duct dilated with calculi. I pressed my fingers on the parietes immediately over the upper end of the wound and pushed the stones forward into the gall-bladder. They were then extracted with long-handled forceps. They were two in number, one an eighth of an inch in its longest diameter, the other over half an inch and much faceted. I then passed the lithotomy sound four inches up the bladder and duct, reckoning from the wound on the surface of the bladder. After deliberate exploration no calculi could be felt. A stout red rubber tube was placed in the bladder, the thick edges of the wound were united with silkworm gut sutures, but the walls of the gall-bladder were not included in the sutures as they adhered firmly to the parietes. The wound was dressed with alembroth gauze; towels covered externally by a mackintosh were placed over the part and round the right flank. The operation was concluded at 10.35 A.M. Free oozing took place; at 7.20 P.M. it was simply sanious, but at 9 P.M. bright-green bile escaped. At 9 A.M. on May 27th much yellow bile came away. On the morning of the 28th the temperature reached its highest, 100.2° in the axilla; a very free discharge of bile occurred; the patient then declared that she was at last absolutely free from pain. After the 29th the temperature fell to normal. On June 16th the patient left the hospital; the fistula had closed. On July 17th I saw her; she was in good health; there was neither pallor nor jaundice, nor swelling in the region of the gall-bladder. On Oct. 19th she had a severe attack of pain, followed by jaundice next day. On the 24th I saw her; the jaundice was passing off. The fistula remained closed. Early in December I saw her again; she had felt local pain on the day before. On Dec. 23rd the patient was seized with severe pain in the region of the gall-bladder; next day her friends noticed that she was deeply jaundiced. On Jan. 1st, 1895, she felt better and came to see me at the hospital. The conjunctivæ were yellow. No enlargement of the gall-bladder could be detected. A few days later she was attacked with bronchitis and was laid up nearly a month. There was much local pain all the time. After getting up and working for a few days she felt a sharp attack of pain; no jaundice was observed, and the suffering soon passed off. On Feb. 21st I saw her again. She had grown thinner, but her complexion and appearance were healthier than at any other time since she had been under treatment. On June 15, 1895, she visited the hospital in excellent health, free from jaundice and pain. The fistula remained closed."²

At the last operation Mr. Doran suggested that the large stone he removed might have come down the hepatic duct after my operation, and it seems to me almost impossible that a stone of irregularly rounded shape, and more than half an inch in diameter, could have been passed over in the thorough examination which I made if it were anywhere outside the liver. Moreover, it would appear from the history that other stones had been left after Mr. Doran's last operation. There is also evidence to support the view that the bile-ducts may be dilated within the liver substance and may form a receptacle for calculi. Mr. Knowsley Thornton has put on record a case in which he removed over 400 stones from a cavity in the liver close to its anterior surface—a cavity which from its situation must have been a dilatation of a comparatively small duct. On the other hand, in the case under consideration it is obvious that from the commencement of the patient's illness until the bile flowed freely from the wound

after Mr. Doran's last operation the chief trouble was due to obstruction of the cystic duct, and that during the whole of that time there was only occasional obstruction of the hepatic or common bile-ducts. There seems to me to be a considerable weight of evidence in favour of the view that when the patient lifted the heavy basket in August, 1893 the big calculus which Mr. Doran removed at the third operation was forced into, and became jammed with others in the cystic duct and that I failed to discover them. The difficulty in this case is not unique, for from what I know of other men's work there can be no doubt that stones of considerable size may quickly pass down the hepatic duct or that they may be hidden away in corners of the ducts in a most extraordinary manner.

CASE 8. *Operation for four gall-stones found respectively in the gall-bladder and in the cystic, hepatic, and common ducts.*—The last of these cases was that of a woman who was under the care of Dr. Tresilian of Epsfeld, and she sought advice mainly on account of yellowness of the skin. She was twenty-eight years of age, had been married nearly five years, and had no children. Early in 1892 she had had an attack of pain in the region of the gall-bladder, lasting a few hours, accompanied by slight jaundice and followed by discomfort for a week. She got quite well, and remained so till Dec. 11th, 1893, when she had another and more severe attack of pain lasting three days. This was accompanied by jaundice, the absence of bile from the stools, and its presence in the urine. These symptoms did not pass off and the patient began to lose flesh. In January, 1894, there was another attack of pain followed by a constant aching in the hepatic region. The patient was admitted to the Samaritan Free Hospital on Feb. 12th. Constipation was then extreme, but a stool passed the day before the operation, although very pale, was not absolutely devoid of bile. The gall-bladder was felt distended and tender, and the liver dulness was slightly enlarged. The patient was not a strong woman; she said she had had rheumatic fever four times, and there was a slight, harsh systolic aortic murmur. Otherwise she seemed fairly healthy, but was of nervous type. Her mother was supposed to have shown symptoms of gall-stones. On Feb. 17th I opened the abdomen over the gall-bladder. There was no adhesion to the abdominal wall, but the omentum was extensively adherent around the gall-bladder. After separating the adhesions I opened the bladder. It contained no bile, but about an ounce of white secretion and two stones. The first of these was barrel-shaped, with a facet at each end, although there was no sign of a stone having been placed in front of it. Probably before the ducts became occluded, when the gall-bladder was liable to distend and collapse, this stone occasionally changed its position, sometimes one end and sometimes the other being opposed to the deeper calculus. The second calculus was of similar shape, but its inner end had two facets on it and was therefore somewhat wedge-shaped. These stones were removed with the greatest ease. After I had sponged out the fluid in the gall-bladder I passed a finger into it, and by manipulation with the fingers of the other hand in the peritoneal cavity I felt two openings very far back in the cavity of the bladder and could touch a stone in each, whilst outside the bladder I could define these. I judged that my finger was in the dilated cystic duct, the curves of which had been to a great extent straightened, and that I felt one stone in the hepatic duct and one in the common bile-duct, both these stones being of elongated shape. I attempted to remove the lower one, but it was necessary first to dilate the opening. In endeavouring to pass a forceps into the duct I suddenly found that I was able to push its closed blades a considerable distance onwards, and after this I could not find the stone. A careful examination failed to show any sign of rupture of the duct, and therefore I presume that the stone was pushed into the bowel. It was never found in the stools although carefully watched for, but possibly it was broken up by the forceps into small fragments. I next endeavoured to get out the upper stone, but although I could feel the lower end of it distinctly I failed by any means that I tried to extract it until I enlarged the opening upwards with a knife, in doing which I pierced the stone, and it at once broke into many pieces. Almost immediately after the stone broke bile flowed into the bladder, and this facilitated the removal of the fragments. When these had been extracted or pushed out by the fingers in the peritoneal cavity the fundus of the gall-bladder was sewn to the edge of the external wound, and a drainage-tube was inserted as in the two other cases. In

² See note 1.

this case also I placed a glass drainage-tube in the loin pouch. Convalescence was uneventful. The highest pulse was 96. The temperature in the vagina rose to 101.4° in the evening of the second day after the operation, but came well down, as low as 99° F., on the fourth day. On the fifth day the patient's condition was satisfactory in every respect. A saline purge was administered in repeated doses and was followed by sickness, distension, abdominal pain, and a rise of temperature to 101.2°. All attempts to move the bowels by purgatives were stopped, and although the patient vomited a great deal of green fluid the sickness gradually ceased, the temperature fell, and the pain passed off. On the seventh day some very hard masses of faeces were passed after an enema had been administered, and the bowels gave no further trouble. The glass tube was removed forty-eight hours after the operation. There was little discharge of bile from the wound at any time, the urine quickly ceased to contain bile, the stools became normal, and the jaundice very slowly disappeared. The patient went home three weeks after the operation, but it was six weeks before the wound healed, and it reopened four times, discharging a little matter and quickly healing again each time. The last occasion was in July. On Feb. 22nd, 1895, more than a year after the operation, the woman was quite free from irritation; the cicatrix was merely a line with a slight pucker at the point where the drainage-tube had been. The patient had a very sallow complexion, and she said that this was sometimes more obvious than at others. She had had no pain in the region of her liver since the operation, and had been able to do her house-work without trouble. She said that she sometimes felt depressed and lazy, when a purgative would put her all right again. I think there is no doubt that she had been neglecting to attend to the condition of her bowels.

Portman-street, Portman-square, W.

THE PHYSICS OF CARDIAC SOUNDS AND MURMURS.

By JAMES T. R. DAVISON, M.D. EDIN.,

FORMERLY RESIDENT PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY.

(Concluded from p. 1569.)

It has been seen that the recoil of the aortic wall cannot throw the semilunar valves into sonorous vibrations, because a membrane is not thrown into sonorous vibrations when it is distended by a mass of liquid. If, however, the semilunar valves are incompetent then the recoil of the aortic wall will give rise to the production of a stream of liquid which will regurgitate into the ventricle. Here again there are the two necessary elements for the production of a sound or murmur—viz., a stream of liquid, and the aortic surface of the membranous semilunar valves against which this stream will impinge as it rushes past the aortic orifice, and, inasmuch as this stream will be a relatively slow one, a murmur and not a sound will result. The murmur will also be best heard near its seat of production.

If the semilunar valves are completely destroyed a ventricular diastolic murmur will still be heard. How is this murmur produced? Let the aorta of an excised heart be firmly ligatured; let the greater part of the left auricle be excised, as also the mitral valves; let water be now poured into the left ventricle from the mitral orifice. There are now exposed to view the left ventricle filled with water and the mitral orifice. Let the nozzle of a gum elastic syringe filled with water be introduced into the ventricle through the mitral orifice. If now the end piece of a binaural stethoscope be applied to any part of the external surface of the ventricle and the syringe be compressed, the direction of the nozzle being such that the stream of liquid will impinge against the inner surface of the ventricle in the vicinity of the stethoscope, then a well-marked blowing murmur is heard. It can thus be demonstrated that a muscular membrane enclosing a liquid can be thrown into sonorous vibrations, which will be heard as a blowing murmur when a stream of liquid is made to impinge against its internal surface. This is the explanation of the diastolic murmur heard in aortic incompetence even after complete destruction of the semilunar valves; the regurgitating stream of liquid impinges against the internal surface of the ventricular wall and throws

it into sonorous vibrations; the murmur is here best heard below the position of the semilunar valves, for it is there that its seat of origin lies.

I will now examine the mode of production of the first sound. The muscular origin of this sound may be easily dismissed, not only because, as has been theoretically demonstrated, a cardiac contraction cannot give rise to a sound, owing to its absence of tetanic character, but if a stethoscope be applied to the biceps of a man and this muscle be made to contract powerfully no sound is heard approaching to the first cardiac sound, although here the acoustic conditions would be much more favourable for the audition of a sound if a muscular contraction could give rise to it.¹ If the aorta of an excised heart be firmly ligatured and the left auricle be slit up or excised, so as to expose to view the auricular surface of the mitral orifice, and if now the liquid contents of a large gum elastic syringe be forcibly driven into the ventricle from the auricular surface of the mitral orifice the following takes place: the ventricle becomes distended with fluid, and in its distended condition the mitral valves close in and completely shut the mitral orifice. Exactly the same result is obtained if, instead of injecting liquid, air be forcibly injected into the ventricle. As in the case of the semilunar valves, so also here it is the anatomical relations existing between the mitral valves and the internal surface of the ventricle that force these valves to completely close the mitral orifice in diastole of the ventricle, when the distension of this cavity has been produced by the forcible injection of liquid or air. The valvular flaps are so attached between the fibrous ring of the orifice and the columnæ carneæ that, when the ventricle distends, a space is left between each flap and the ventricle wall. When liquid is made to distend the ventricular cavity it presses equally in all directions. Placed between the ventricular wall and the valvular flaps, it will tend to separate them, and, in doing so, will push the ventricular wall outwards and the mitral valves inwards and backwards. But the fluid which is exercising this liquid pressure is being introduced by the mitral orifice. Therefore a moment will arrive when the pressure within the ventricle will equal that which is being exercised at the mitral orifice, and when that moment arrives the valves which were closing will have closed completely. These valves have closed, however, not owing to any reaction on the part of the ventricular muscle; they have closed solely owing to the liquid pressure which was being exercised behind the flaps, and this liquid pressure was being directly introduced through the mitral orifice, the perfect closure of the valves being coincident with, and the result of, the last drop that entered the ventricle. By substituting the gum elastic syringe for the left auricle it is seen how the mitral valves are closed by the auricular contraction; and this closure, it is important to bear in mind, can only take place at the latter part of the contraction, for the first and greater part of the auricular contraction is occupied with the distension of the ventricle, which distension must of necessity first take place in order that the anatomical relations of the valves may place these under favourable conditions for their rapid and complete closure. Now, applying the principles of production of sounds and murmurs by means of fluid streams impinging against membrane, the nature of sounds and murmurs produced at the mitral orifice may be studied. During the auricular contraction a stream of liquid is rushing past the mitral orifice into the ventricle, but towards the end of the contraction the mitral valves are suddenly thrown in against the orifice, and the stream impinges against them in this act, and as this stream is passing rapidly the valves are thrown into sonorous vibrations, which produce a sound. The first sound is thus the direct result of the auricular contraction. Its intensity will depend upon the relative strength of the contraction; its pitch will depend upon the physical condition of the valves, being lower the thicker the membranes are.

A difficulty will at once be seen to arise with this interpretation of the first sound. We have been taught to consider the cardiac impulse as due to ventricular contraction and the first sound as synchronous with the impulse. Now I do not wish to digress from the main subject of this paper by discussing the cause of the cardiac impulse; suffice it to

¹ Over ten years ago, while occupying the post of house surgeon at the Royal Southern Hospital of Liverpool, I accidentally found out this experiment while washing out a heart under a water-tap after a post-mortem examination. I then showed this experiment to some of the physicians and surgeons present at the hospital. Subsequently I learnt in Dr. Walpole's treatise on Disease of the Heart that this experiment had been previously performed by Baumgarten. It is strange that text-books on physiology make no mention of the experiment.

say that the question is still an open one. For my own part, I believe the impulse to be due to auricular contraction, which, distending the ventricle, throws it against the chest wall; and in proof of this I have sometimes, by placing one finger over the apex beat and another over the carotid pulse, distinctly observed that the former precedes the latter. Leaving aside the cardiac impulse, whose mode of origin is still a matter of dispute, I will take the carotid pulse as a more reliable sign for timing the sounds and murmurs of the heart; but even here the difficulty does not altogether disappear. If the first sound is produced by the auricular contraction one would naturally expect that this sound would precede the carotid pulse, which is the result of the ventricular contraction. As a matter of fact, according to ordinary methods of observation, in many cases the first sound and the carotid pulse appear to be synchronous. There are some cases, however, where the first sound is distinctly observed to precede the carotid pulse. Now, the first sound is only produced, as has been seen, towards the end of the auricular contraction; the ventricular contraction follows immediately; and it is known how rapidly the pulse wave is transmitted, reaching the carotid artery long before the ventricular contraction comes to an end. The carotid pulse must, therefore, follow close upon the first sound—so close that in many cases, to ordinary methods of observation, both appear to be synchronous, though they actually are not so.

Returning now to the examination of murmurs produced at the mitral orifice, it has been seen how a rapid and sudden stream, impinging against the mitral valves, gives rise to a sound. If the rapidity of this stream be sufficiently slowed, so that, instead of being abrupt and sudden, it be somewhat prolonged, then, according to the acoustic principles above enunciated, the sound will be changed into a murmur. This slowing of the rapidity of the stream will take place when the auricular muscle is badly nourished and fatigued, while the mass of circulating blood does not diminish in quantity. Hence the production of the so-called functional murmurs of chlorosis and fevers. These murmurs, being caused by the somewhat delayed auricular stream impinging for a somewhat longer than the normal period against the mitral valves, will actually precede the carotid pulse, but, for reasons given above, in many cases they will appear to be synchronous with it. These murmurs may likewise be produced at the aortic orifices, but, inasmuch as the ventricular are more powerful than the auricular muscles, and therefore less prone to fatigue, they will be less frequent there than at the apical orifices. In mitral stenosis the narrowing of the orifice prevents the auricle from contracting rapidly, and this forces it to take more time in voiding its contents into the ventricle; therefore the rapidity of the auricular stream will be slowed and the first sound will be replaced by a murmur. This murmur will be rough in character if the auricle be greatly hypertrophied, so that the stream, as it rushes through the mitral orifice, impinges with force against the membrane formed at the edges of the orifice. This murmur, known as the mitral presystolic, generally ends with a sound. This can be imitated in the experiment with the intestine and gum elastic syringe. If the syringe be compressed somewhat forcibly there is obtained, instead of a soft blowing murmur, one rough in character. If towards the end of the compression greater and sudden force is imparted to this, then a rough murmur is obtained, which ends in a sound. In mitral stenosis, with hypertrophy of the auricle, the contraction will be at first powerful, but slow; yet towards the end of the contraction, when the auricle is nearly emptied, this, having now only a small quantity of blood to drive into the ventricle, will be able to inject it with greater rapidity and suddenness, the stream in its latter part will be quickened and sudden, and thus the rough murmur will end in a sound. The same phenomenon can be sometimes observed in the case of the ventricle in aortic stenosis. In some cases of mitral stenosis the sound is often unaccompanied by the murmur, except under special conditions. For example, if the stenosis be not very marked, and the hypertrophy of the auricle be well established, then it may be possible that the presystolic murmur will be absent when the patient is standing up and only present when he is in the recumbent posture. In the erect posture the heart works with greater activity than in the recumbent posture; hence in the former the auricular contraction may produce a sufficient rapidity of stream to give rise to a sound, while in the latter the lessened activity of the auricle may prolong the contraction to that degree which is necessary for the production of a

murmur. In the same way is explained the frequent disappearance of the functional murmurs in chlorosis during the erect, and their reappearance in the recumbent posture. In like manner other cardiac murmurs are only heard in the recumbent posture—that is, they are only heard when the respective muscles whose contractions are the direct cause of the murmurs act with greater repose and so prolong the duration of the streams which impinge against the membranes. But, again, a presystolic murmur may only be heard when the patient is made to walk quickly. In this case, when at rest, the hypertrophied auricle is capable of voiding itself with sufficient rapidity to produce only a sound, but when the patient is made to walk quickly the circulation increases greatly in activity, and, as a result of this, the blood accumulates behind the stenosed orifices—that is, it accumulates in the left auricle—and now this auricle, being overfilled, is unable to void itself, in spite of its hypertrophy, with the same rapidity as before; hence the duration of the stream is prolonged and a murmur accordingly takes place, which, however, as already explained, may end in a sound. The same explanation holds good for the appearance and disappearance of at least all murmurs due to stenosis after activity and after rest. The soft murmur which often precedes the ordinary presystolic murmur in mitral stenosis is produced by the slow and prolonged current of blood which, entering the auricle from the pulmonary veins, continues to pass into the ventricle and to impinge against the membrane at the stenosed orifice, before the auricle begins its contraction. If the mitral valves are completely destroyed, and no stenosis be present, then, unless the auricle be extremely hypertrophied, its contraction will be unattended either by a sound or a murmur. If, however, under this condition extreme hypertrophy of the auricle be present, a sound of low pitch may possibly be heard, but this sound will not be due to sonorous vibrations of any valvular membrane. If the pulmonary artery of the excised heart of an ox be firmly ligatured, and, the right auricle having been opened and the bicuspid valves removed, the right ventricle be filled with water, and the nozzle of a gum elastic syringe also filled with water be introduced within it, and if now the gum elastic syringe be compressed so that the liquid will impinge against the inner surface of the ventricle, a blowing murmur will be heard by means of the stethoscope applied to the external surface of the ventricle; if the syringe be very rapidly and forcibly compressed the murmur will be replaced by a sound. It is thus seen that when a muscular membrane enclosing a liquid has a fluid stream directed against its internal surface, provided the stream be very forcibly injected, the muscular membrane will be thrown into such sonorous vibrations as to give rise to a sound. This experiment cannot be produced with a small heart such as that of a sheep, for the force necessary to produce the required rapidity of the stream splashes the liquid out of the cardiac cavity. I have, however, succeeded in obtaining the sound when working with the right ventricle of an ox's heart. It may be asked, Why does not the left auricle ordinarily give rise to a sound, as its stream during its contraction strikes against the inner surface of the ventricle? Because, when the auricular contraction begins, the ventricle is already to some extent filled with blood, and therefore the auricular stream due to the contraction will not impinge directly against the muscular membrane, but against the liquid already contained within the ventricle, which conditions will not be sufficient to produce a sound. If, however, the auricle be extremely hypertrophied, then its stream, during contraction, may force itself through the contained liquid in the ventricle, so as to impinge directly against the inner wall of the ventricle, and produce a sound. This mode of production of a sound may be possible, but it must be rare, for in those greatly hypertrophied hearts where one might look for it the ventricle is also enlarged and must contain more blood before auricular contraction begins, and, therefore, its wall must be relatively more separated from the mitral orifice at the time that the powerful auricular stream enters the ventricle.

Lastly, I come to the consideration of the regurgitant murmur produced at the mitral orifice—the ordinary mitral systolic murmur. The fact that this murmur may exist without any stenosis of the aortic orifice might at first sight appear to destroy the truth of the acoustic principles I have enunciated. It might be argued that in the absence of aortic stenosis, the ventricular contraction being rapid, no murmur could be produced at the mitral orifice; for although the membrane against which the mitral regurgitant stream

would impinge would be present, yet, the ventricular contraction being rapid, the conditions existing would favour the production of a sound and not that of a murmur. It must, however, be remembered that the first part of the ventricular contraction is unaccompanied by any sound at the aortic orifice, and that it is only at its latter portion that the semilunar valves undergo the act of closure, and in this act present themselves suddenly against the ventricular stream that is entering the aorta. The strong ventricular stream thus impinges only for a moment against the membranous surface of the semilunar valves. In mitral regurgitation the ventricular stream impinges against the remains of the mitral membrane during the whole of the ventricular contraction; it is thus a relatively prolonged stream that impinges against a membrane, and hence the production of a murmur.

With regard to the mode of production of arterial murmurs, the same acoustic principles explain them. If the stethoscope is pressed against an artery part of the arterial membrane is pushed into the interior of the artery, and thus a membrane is opposed against a relatively prolonged stream. In aortic regurgitation the diastolic arterial bruit heard over the femoral artery is produced in the same manner.

In conclusion, to avoid confusion, I have omitted to state the combination of murmurs and sounds which may be produced at both orifices. If the sounds and murmurs of the heart are to be explained by the acoustic principle I have related, then it might be advisable to name them according to their mode of production and locality in which they are produced. Thus, the first sound is the auricular sound, and the second the ventricular. Murmurs produced at the mitral orifice and due to auricular contraction are mitral auricular systolic murmurs; these will be practically synchronous with the carotid pulse when they are functional in character—that is, when they simply replace the auricular sound owing to fatigue of the auricular muscle; they will precede the carotid pulse when they are organic—that is, when they are produced by marked delay of the auricular contraction owing to obstruction of the mitral orifice. Murmurs produced at the mitral orifice, due to ventricular contraction, are mitral ventricular systolic murmurs and are synchronous with the carotid pulse. Aortic ventricular systolic murmurs are produced at the aortic orifice owing to the ventricular systole; when these are due to stenosis of the orifice they will be synchronous with the carotid pulse; when functional—that is, due to simple fatigue of the ventricular muscle—they will succeed the carotid pulse; when due to undistensible conditions of the aorta they will be practically synchronous with the carotid pulse. Aortic systolic murmurs (regurgitant aortic) are due to the systole of the aorta and succeed the carotid pulse.

Buenos Ayres.

MILK INFECTION.

By ROBERT BOXALL, M.D. CAMB., M.R.C.P.
ASSISTANT OBSTETRIC PHYSICIAN TO THE MIDDLESEX HOSPITAL.

THE publication of "An Occurrence of Milk Infection" in THE LANCET¹ has induced me to record a similar occurrence which took place ten years previously in the General Lying-in Hospital. Between July 5th and 13th five patients who had recently been delivered and six other members of the establishment were affected, the latter in some instances even more severely than the patients. Each case presented much the same symptoms: abdominal pain and tenderness more or less severe, ushered in by a slight rise of temperature with diarrhoea and tenesmus and followed by loss of appetite, extreme fetor of the breath, and a very coated, foul tongue. The stools were usually much relaxed, slimy, very irritating, and in one case developed the character of the green chopped spinach motions of an infant, and set up aphthous ulceration of the thighs wherever they came into contact. Later, moreover, towards the end of the first week of the illness, in some of the cases the mouth became sore. This soreness often began at the roof of the mouth, and aphthous ulcers subsequently made their appearance along the sides of the tongue on its under surface and along the inner side of the cheek, selecting those parts with which the teeth came into contact. The soreness was accompanied by considerable swelling. Some

of the patients had lacerations about the vulva more or less severe, and in each case the open surface began to ulcerate rapidly and developed a similar aphthous character about the same time as the ulcers in the mouth began. The general condition, meantime, was not affected beyond the extent of the local mischief, and in all the lying-in women the course of the puerperium proceeded uninterruptedly towards recovery. In looking for the cause of the illness it was not difficult to satisfy oneself that the milk-supply was at fault. In the first place, inasmuch as this epidemic among patients and nurses occurred during a period of rather more than a week, it was apparent that some noxious element must have been introduced into the situation at that time only. In the second place, the illness occurring in patients in isolated wards (three in each, but only one affected), where, in view of the possibility of the introduction of infectious disease, every precaution was taken to prevent the spread of infection from one to another, and occurring in the cook and in five nurses, each kept strictly to her own ward (though in two cases attending to patients also affected), this without doubt told against infection through the air. In the third place, the initial symptoms were those of an irritant poison taken into the alimentary canal. But the patients, at any rate, were on a strictly regulated diet, so that no ordinary indiscretion as regards food would account for the illness. On the other hand, it may be mentioned that the diet of the patients during and for the first three days after labour consisted largely of milk, and that all those affected had but recently been delivered. Moreover, the nurses affected and the cook were among those members of the resident staff who were in the habit of drinking milk at dinner and supper instead of beer. Furthermore, in the milk-supply itself at that time evidence pointing to the cause of the epidemic was afforded. For ten days or rather more the milk supplied to the hospital presented the following characters, for which I can vouch from personal observation, my attention having been drawn to it in the first instance by its peculiar taste, which I can only describe as rather earthy. The milk presented a deep yellow colour, imparting to it a rich appearance, gave forth a faint, sickly odour, and though kept in a refrigerator very quickly turned sour. Several of the patients and nurses complained of its taste, and several of those affected, even before I had occasion to suspect the milk, said that the milk did not agree with them. And, lastly, on July 12th a fresh milk-supply was obtained and the milk was boiled as soon as received at the hospital; the epidemic then came to an end.

In what way the milk had become infected I am unable to say, and the milkman either could not or would not afford any clue. When questioned as to his customers, with a view to tracing other cases, he asserted that the hospital absorbed the whole of the milk sent by one farm, and none other; that he supplied no one else from the same source; and that he devoted that special supply to the hospital use because it appeared rich and good. But as the consumption in the hospital varied much from day to day, according to the number of patients, unless the dairyman's cows were exceptionally accommodating to meet the varying requirements of customers, it is obvious that there must have been a remainder which was unaccounted for. The dairyman stated that the farm had been inspected and that no disease was found among the stock. He owned to the practice of adding annatto to the milk, and gave me a sample which, as far as could be ascertained, in itself was free from suspicion. The conclusion which I myself came to at the time was that the disease must have originated in some disease in the cow itself. The following table gives the dates of admission of the patients and of the appearance of the first symptoms and aphthous patches:—

Case.	Admitted.	First symptoms.	Aphthous patches.	
			In mouth.	At vulva.
1	1884. July 3rd	1884. July 5th	1884. July 11th	1884. July 9th
2	" "	" "	" 12th	" 13th
3	" 5th	" 8th	None	None
4	" 6th	" 11th	July 13th	July 11th; on buttocks, July 14th
5	" 11th	" 13th	" 15th	None

The cases above recorded appear to correspond in every respect with those alluded to by Dr. Niven in the paper to

¹ THE LANCET, Jan. 19th, 1895.

which reference has already been made, except that he makes no mention of the subsequent appearance of aphthous patches such as were often observed in the hospital cases. That these patches, both in the mouth and about the vulva, partook of the nature of true aphthæ I think there is little room to doubt. I regret that for want of time I omitted to subject the patches to microscopical examination. The peculiar green stools in Case 4 were remarkable, and, considering that as a rule a case of thrush only occurred on an average once in about 100 infants born in the hospital, it seems rather more than a coincidence that two infants should have been affected with thrush during this epidemic, one in the same ward as Case 4, and the other in the same ward as Case 5. It is possible that the *oidium albicans*, in addition to the other poison, whatever its nature, may have been conveyed also by the contaminated milk. In any case, I consider that it is a subject for congratulation that the hand-fed children, of whom there were several in the hospital at the time, were all taking condensed instead of cow's milk. In November of the same year an isolated case of the same character as the others came under my observation. On admission to the hospital the patient was not well, having had diarrhoea and griping pains for two or three days. From her mother I subsequently ascertained that she had a son at home similarly affected, and that she herself, daughter, and son were in the habit of taking a glass or two of milk in the day, and that the milk had had a peculiar taste and smell, was of a "funny yellow colour," and rapidly turned sour, so much so indeed that complaint had been made to the milkman. The mother herself had not been affected. Dr. Niven draws attention to the fact that in the Manchester epidemic many appear to have escaped. It was the same with patients and members of the resident hospital staff. Of the sixteen patients admitted between July 2nd and July 12th—i.e., between the admission of the first patient who fell ill and the date on which the milk-supply was changed—five only were affected, and not more than half of the resident staff of the hospital, though all probably partook of milk in a greater or less degree, each patient taking at least two pints in twenty-four hours for the first three days after delivery. As until the supply was changed it was not customary to scald the milk received into the hospital, the value of raising infected milk to boiling point with a view to warding off infection could not be determined. The question raised by Dr. Niven of the protective value of mere scalding is an important one. In conclusion, I may add that treatment was based on the assumption that the illness was due primarily to some irritant in the intestinal tract, and, with a view to eliminate the poison, a calomel purge was administered at the outset. If the diarrhoea continued the purge was followed by castor oil and opium, and later by quinine and opium in the form of pill.

Weymouth-street, W.

SECONDARY HÆMORRHAGE IN A CASE OF NECROSIS OF THE FEMUR; LIGATION OF THE FEMORAL AND EXTERNAL ILIAC ARTERIES UNDER COCAINE; RECOVERY.

By R. N. HARTLEY, B.S. LOND.,

HONORARY SURGEON, LEEDS GENERAL INFIRMARY, ETC.

THE interesting report of a case of ligation of the femoral artery, by Mr. Southam of Manchester,¹ for secondary hæmorrhage suggested the desirability of putting on record the following case, the facts of which speak for themselves.

A boy aged sixteen years was sent to me in March, 1889, on account of long-standing necrosis of the right femur. Briefly, the history was an attack of typhoid fever in 1886, followed by an acute periostitis of the whole shaft of the right femur, with some inflammation, apparently, of the hip and knee-joints. The hip was stiff, but the head of the femur remained in its socket; the knee seemed partly subluxated and the heel rather drawn up by the calf muscles. The thigh was much thickened, and several large sinuses discharged daily much pus. The irregular mass of new bone evidently enclosed a large loose sequestrum. The

boy was ill and worn from the long-existing suppuration, and on March 27th, 1889, the sinuses were dilated under ether for better examination, and through an opening made in the new mass of bone a large sequestrum was removed in two pieces, evidently the remains of the whole diaphysis of the femur. There was a very large irregular cavity, which was cleaned as thoroughly as possible and packed with strips of lint dusted over with iodoform. There was no serious bleeding during the operation. All went well till the following Sunday morning when I was hastily summoned to find the boy lying in a pool of blood, blanched, almost pulseless, and only partially conscious. It was practically impossible to make out the source of the bleeding, except that it came from the inside of the sloughy cavity and was probably arterial; and as promptness of action was imperative fifteen drops of a 2 per cent. solution of cocaine hydrochlorate were injected under the skin over the upper part of the femoral artery, and with the help of a nurse the skin was incised, the artery exposed, and a double catgut ligature passed round it at a point about two inches below Poupart's ligament. The ligatures were separately tied upon the artery, and the vessel was divided between them. The hæmorrhage seemed to be quite controlled, and during the day the cavity of the thigh was emptied of clot and packing, cleansed, and repacked. All was quiet for a week, when again on the Sunday morning following I was called, to find that the boy had had a second similar severe hæmorrhage and seemed on the point of death. An injection of cocaine above Poupart's ligament allowed a slightly curved incision to be made a little above it, and a dissection was carried through the lower part of the abdominal wall, the peritoneum was pushed up, and a double catgut ligature passed (as before) round the external iliac artery, the vessel being tied at two points and divided between them. The wound healed rapidly and without trouble, and after this there was no more bleeding at any time. Great care was taken, in the nursing &c., to preserve the vitality of the limb, and the filling up of the thigh cavity was somewhat tedious, but the wearing of a Thomas's knee-splint enabled the patient to get about more comfortably, and the subsequent division of the tendo Achillis greatly lessened the shortening of the limb. The boy is now a healthy man aged twenty-two years, learning the mysteries of "business," but with a very vivid recollection of his experience of six years ago.

Looking back, it is easy to say that it would have been better if the femoral artery had been ligatured higher up in the first instance, while the particular method of tying an artery in its continuity, the use of cocaine for the purpose, and other points might furnish suitable material for comment. The object, however, of this short communication is simply to record the main facts of the case and to express the opinion that the trustfulness and courage of the boy greatly lightened a most anxious and critical experience in a surgeon's life, and helped to avert a "surgical catastrophe."

Leeds.

A CASE OF EMPYEMA WITH COMPLICATIONS.

By SURGEON-CAPTAIN S. G. ALLEN,

LATE ASSISTANT PATHOLOGIST AND CLINICAL OPHTHALMIC ASSISTANT, ST. MARY'S HOSPITAL.

WITH reference to an article by Mr. Stephen Paget which appeared in THE LANCET of May 4th, recording the occurrence of cerebro-spinal symptoms of an obscure character during the treatment by irrigation of certain cases of empyema, I beg to forward the following extracts from the notes of a case of somewhat similar character which has recently come under my observation.

A man aged thirty-five years was taken ill early in January last with left-sided pleurisy, followed by croupous pneumonia of the left lung, the right lung also becoming affected shortly afterwards. This double pneumonia ran a favourable course for a time, the temperature returning to normal by the end of the second week of illness, and the physical signs showing that the consolidation of the lungs was clearing up. This process of resolution gradually came to a standstill, however, and the symptoms became of a more chronic character. His condition varied from

¹ THE LANCET, May 25th, 1895.

day to day, but no noteworthy change appeared in the condition of the chest till early in March, when there was found to be some effusion into the left pleural cavity. This rapidly increased, so that by the 11th the aspirator was used to relieve pressure effects. As the fluid drawn off was found to be purulent I established free drainage of the pleural cavity by resection of a portion of the sixth rib in the axillary line. A large quantity of healthy-looking pus escaped at the time of the operation. His temperature fell to normal, and his general condition began at once to improve. No irrigation was used at first; but a few days after the operation the discharge had become much thinner, of saffron appearance, and with slight odour. Consequently a weak iodine solution (the colour of pale sherry) was used daily from this time to wash out the pleural cavity. Under this treatment the discharge became again healthy in character and gradually diminished in quantity day by day. The compressed lung re-expanded in a satisfactory manner and the remaining consolidation cleared up. For six weeks the daily irrigation was continued, and the patient progressed satisfactorily, the drainage-tube, which was originally 7 in. long, being gradually reduced to 2 in. On May 1st, however, his temperature rose to 101° F., and it was thought by the medical officer (Sergeon-Major Simpson), under whose care he at that time was, that a small collection of pus existed, which was unable to escape through the shortened drainage-tube. A long soft tube of small calibre was consequently passed down the sinus, and a small quantity of pus was evacuated. Some of the iodine solution was then carefully injected down this tube (no distension could have been caused by this, as the fluid during the injection escaped alongside the tube); while this was being done the patient was suddenly attacked with syncope. The attack was so severe that it was at first thought he had died suddenly, but by means of artificial respiration and the use of stimulants he recovered somewhat. I saw him about three-quarters of an hour after this seizure. He was then in a condition of deep stupor, neither speaking nor understanding when addressed. He groaned and cried out frequently as if in pain. His eyes were firmly closed, and he resisted any attempts to open them. On raising the lids, however, the pupils were seen to be dilated and equal. The pulse was rapid (130) and weak in volume. The respiration was irregular. At the time of the attack Cheyne-Stokes breathing was noticed for a time. No motor paralysis was present, but spasmodic contractions of the fingers took place from time to time. There appeared also to be increased excitability of the sensory nerves, as when touched or moved the patient resented it and cried out. Owing to retention of urine the catheter had to be passed later in the day. This excited well-marked spasm of the urethral muscles. On the following morning the condition of stupor and general state was unchanged, but during the day he passed his urine and motions in bed. His temperature was 99°. No change occurred till the morning of May 3rd, when (after a sleep) he was found to have regained consciousness. His temperature was very low (96.4°), but rose to 98° by the evening. His mental condition continued to be very disturbed for the following three days, and he suffered from attacks of delirium, from which, however, he could be recalled by being spoken to. The pupils after his return to consciousness gradually diminished in size, but the left remained somewhat larger than the right; reaction, both direct and consensual, was normal. The temperature kept below 99°, and he was comparatively well till May 9th, when he was suddenly seized with severe abdominal pain and fever (101.4°). There was tenderness in both iliac fossæ, but no tumour or muscular rigidity. The pain was continuous in character, but every now and again it increased in severity. The bowels had been freely moved on the previous day; there was nothing abnormal about the stools and no intestinal distension. The urine contained a faint trace of albumen. The discharge from the sinus had become more abundant, but was quite sweet. Since his seizure on May 1st no further attempt at irrigation had been made. On the three days following this attack of abdominal pain—May 10th, 11th, and 12th—he had an attack of shivering, with rise of temperature every afternoon between 1.30 and 4.30. The pain, although still present, became less severe each day. On the morning of May 13th it quite ceased, and his temperature stood at 97.4°. Since then his progress has been most satisfactory. The wound is rapidly closing, and his general health is excellent.

Royal Arsenal, Woolwich.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON SOME AIDS TO RAPID DILATATION OF THE UTERUS.

BY AMAND ROUTH, M.D., B.S. LOND., M.R.C.P. ENG.,
OBSTETRICAL PHYSICIAN WITH CARE OF OUT-PATIENTS AT CHARING-CROSS HOSPITAL; PHYSICIAN TO THE SAMARITAN FREE HOSPITAL, ETC.

IN dilating the uterus rapidly by the method of graduated bougies one occasionally finds a good deal of resistance from rigidity of the cervix. This may be due to the presence of a fibroid in its wall or to cicatricial tissue, but the ordinary rigidity which is encountered is in the cervical zone of nulliparous women. This rigidity has led many operators to commence the dilatation of such cases by the insertion over night of a laminaria tent, which will soften and partially dilate the cervix. As there are risks of septic infection in this procedure, however carefully one may prepare both the patient and the tent, and as the patient is always in an unsatisfactory state after a night spent in such a preliminary dilatation, I have endeavoured to find means by which rapid dilatation may be so aided that tents may be dispensed with. The following are means by which for some years I have been enabled to rapidly dilate uteri so as to digitally explore the cavity without using any form of tent. 1. Drs. Herman and Braithwaite have shown that the cervix is soft and relaxed and partially patent at the end of menstruation. Clearly, therefore, Dr. Braithwaite is right in advising that rapid dilatation should be performed the first possible day after a period has ceased, and this has been my practice for some years. 2. Dr. Champneys has drawn attention to the fact that a non-secreting cervix will not dilate, whether in labour or otherwise. If a rigid cervix can be made to secrete it becomes at once relaxed. To encourage this secretion I have used a wool tampon saturated with glycerine. This is introduced by the nurse two hours before the operation to the top of the vagina against the external os uteri. This causes all the glandular tissues of the cervix to secrete profusely, and the cervix, instead of feeling like a piece of gristle, gets quite soft. I have thought, but have no proof to offer, that this effect is enhanced by the addition of some cocaine to the glycerine, possibly by allaying local spasm, as is said to occur in the "rigid os" of the first stage of labour when cocaine is applied. 3. If the cervix be considered likely to be unusually rigid, I have found unquestionable advantage from passing into the cervix and, if possible, through the os internum, a strip of antiseptic gauze, six or eight hours before the operation, or even overnight. A few bougies may be passed if necessary to enable this to be done, and the vagina and cervix should be first antiseptically cleansed. The gauze should be soaked in glycerine and iodine. At the operation the cervix will be found to be as soft and nearly as dilated as if a laminaria tent had been introduced, whilst the risk is far less, drainage having been encouraged instead of entirely prevented. This process is painless. Of course, if the uterine discharges be offensive, neither gauze nor tents are applicable. These aids to dilatation almost always suffice to permit digital exploration, and if it should be found impossible to admit the little finger in 1 or 2 per cent. of cases, the uterus can be sawed out and packed fairly tightly with gauze for twenty-four hours, by which time it will easily admit the finger. Gauze, in itself a disinfectant, may here be used, whereas a tent would be absolutely contra-indicated. By these aids I have been able to entirely dispense with "tents" for at least five years, both for hospital and private work.

Manchester square, W.

A MIGRATING OVARIAN TUMOUR.

BY HEYWOOD SMITH, M.A., M.D. OXON.

THE migration of ovarian tumours is sufficiently uncommon to make the narration of such a case not without interest. A woman aged fifty-one years consulted me on April 1st, 1894. She had been married twice—

the first time for a year and a half, having one child—this was twenty-one years ago; she was a widow for three years, whereupon she again married sixteen years ago and had two children—the younger fourteen years ago. Her catamenia lasted from the fourteenth till the forty-eighth year. She said she had overwalked herself when young, and had ovaritis twenty-two years ago. If she walked too much she had pain in the right ovarian region, with heat in the vagina. The bowels acted regularly; there was no vaginal discharge. On vaginal examination her uterus was found to be retroflexed and slightly to the right; the uterine sound showed there was a slight hitch at the inner os. The right ovary was enlarged to the size of a small orange. I saw her again at the end of January this year. On Feb. 2nd, on vaginal examination, the uterus was still found to be retroflexed, and on being replaced it at once returned to its abnormal position; the cervix was congested, and on the passage of the sound there was some slight bleeding. There was a small (pin's head) polypus at the os. The tumour of the ovary on the right was rather hard, and it had increased in size. On the 7th I had a consultation with Dr. Cullingworth; he agreed with me that there was a tumour of the right ovary and that it ought to be removed. The operation was performed on the 27th. Dr. Dudley Buxton gave the anæsthetic, and Dr. Mary Scharlieb assisted. An incision of about three to four inches was made, and a tumour was found on the right side the size of an orange; it was adherent to the omentum and to the oviduct, and when these were broken down the tumour came away without a pedicle. Just below the tumour was a hydrosalpinx of about the same size; this was brought to the surface. It consisted of the fimbriated end, and the rest of the tube was traced right across the retroverted uterus to the left side of the pelvis, where it was tied and cut away. No appendages were found on the left side, but the right ovary and oviduct were found to be deep down in the pelvis, on the right. The ovary was small (size of a bean), and it and the tube were removed. The ovarian tumour was a dermoid, and contained cholesterine, hair, and some bony plates. The wound was closed in three layers, and no drainage-tube was used. On March 21st the uterus was nearly in its normal position, very slightly to the right. On the 27th the position of the uterus was normal. The interesting points about this case are—(1) the migration of the left ovary over to the right side; (2) the extension of the oviduct across the pelvis, forming a bridge keeping down the fundus of the uterus; and (3) the rapid atrophy of the other ovary three years only after the menopause. I should be glad to know whether other observers have noticed any such similar migration on the part of an ovary, and to what it may be attributed.

Harley-street, W.

A CASE OF "DYSPHAGIA LUSORIA."

BY T. H. KELLOCK, M.D. CANTAB., F.R.C.S. ENG.,
MEDICAL SUPERINTENDENT, HOSPITAL FOR SICK CHILDREN,
GREAT ORMOND-STREET;

AND

FREDK. E. BATTEN, M.B., B.C. CANTAB., M.R.C.P. LOND.,
PATHOLOGIST TO THE HOSPITAL.

THE term "dysphagia lusoria" is used by Fagge¹ in describing a case reported by Dr. Bayford of Lewes in which dysphagia occurred in a child the subject of an abnormal origin and course of the right subclavian artery; Mackenzie² mentions this symptom as occurring in the same connexion; and Prichard³ has described a case where a fish-bone stuck in such an abnormal artery behind the œsophagus and caused death by hæmorrhage. Referring to Dr. Bayford's case, Fagge suggests that the dysphagia was spasmodic and its occurrence in connexion with the abnormal artery probably only a coincidence; that it may be something more than this we think the following case tends to show.

A healthy boy aged two years and ten months was brought to the Hospital for Sick Children, Great Ormond-street, on the evening of March 6th, 1894, having been severely choked whilst eating an apple; on this occasion nothing could be found in the pharynx, but the child had been affected seriously enough by the accident to warrant his being kept in the hospital that night. He was, however, discharged quite

well on the following morning. On Oct. 30th he was again brought hurriedly to the hospital about 2 P.M. with the history that he had been suddenly choked whilst eating his dinner; he was cyanosed and breathing with some difficulty, and whilst in the casualty room became much worse and ceased to breathe altogether; the trachea was opened at once and artificial respiration performed for about half an hour, but without restoring natural breathing. At the post-mortem examination, twenty-one hours after death, a small blood clot was found in the trachea, which had been opened by division of the fourth, fifth, and sixth rings. A large mass of granular-looking material (probably sausage) was found lying fairly loosely at the back of the pharynx, but it is uncertain whether or not it occluded the upper opening of the larynx. On dissecting the arteries arising from the aorta the following arrangement was found. There was no innominate artery; the two common carotids came off practically together, the left following the usual course, but the right crossing the trachea from the left side just above the sternal notch to reach its usual position on the right side of the neck. The left subclavian came off the arch of the aorta next and followed a normal course; then came the right subclavian, arising from the descending part of the arch and crossing obliquely behind the œsophagus between this and the spine and behind the right scalenus anticus muscle to its usual situation at the root of the neck, this arrangement of vessels closely resembling that described in Quain's Anatomy and elsewhere as due to the persistence of the right aortic root and the abnormal closure of the fourth right arterial arch, which normally remains patent as the right subclavian artery.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

KING'S COLLEGE HOSPITAL.

FOUR CASES OF TUBERCULOUS DISEASE OF THE BLADDER
TREATED BY SUPRA-PUBIC CYSTOTOMY; REMARKS.

(Under the care of Mr. W. WATSON CHEYNE.)

WHEN publishing recently the account of a case of successful cystotomy for tuberculous disease of the bladder, we commented on the small number of patients who had required this treatment. In doing so we did not mention the first two cases of the following series which had escaped our notice. We now give a short abstract of them, and bring before our readers two others which were treated in a similar manner. A curious fact, and one worthy of note, is the sex of these patients, most of the published cases having occurred in women. We agree with Mr. Cheyne in attaching importance to rest as a curative agent in tuberculous disease, but think it better to scrape these ulcerations after the opening of the bladder. Rest alone is not always sufficient to cure tuberculous disease in other parts of the body, yet when the diseased part has been subjected to the action of the curette cure often follows; few would contend, however, that the operation had removed the whole of the disease in the cases which get well after the scraping.

CASE 1.—A man aged thirty-six years consulted Mr. Cheyne in February, 1891. A short time previously he had begun to suffer from frequency of micturition, accompanied by pain towards the end of the act. This had been getting worse, and for the last two days he had been passing urine every two hours; at the end of micturition pure blood was passed, and the pain in his bladder and penis was very severe. The bladder was very tender, both above the pubis and on examination per rectum. There was no enlargement or tenderness of the prostate or vesiculae seminales. The testicles were normal. There was no kidney enlargement or tenderness. The passage of a sound caused great pain. The urine was acid and contained blood and pus. The temperature was

¹ Fagge's Principles and Practice of Medicine, vol. ii., p. 313.

² Medical Times, 1876, vol. ii., p. 457.

³ Illustrated Medical News, Dec. 1st, 1888.

99° F. The patient was pale and thin, and thought he had been losing flesh lately. Some four or five years ago he had had pleurisy and became much emaciated, but subsequently recovered. There was then a question as to tuberculosis. He was put to bed and ordered the usual sedatives. For a few days he improved, but ten days later the acute symptoms recurred without apparent cause. To sum up, he was kept in bed under treatment for six weeks, during which time he had two severe attacks and the prostate became somewhat larger. The diagnosis came to was tuberculous disease of the bladder, and as no progress was being made Mr. Cheyne thought that the time had come for operative interference. Before doing so, however, there was a consultation with a specialist, who saw and figured and located a tumour, which it is believed, was afterwards modelled. Although Mr. Cheyne could not see it and could not accept the diagnosis, it gave him the opportunity required of insisting on opening the bladder. This was done supra-pubically on April 4th. On examining the bladder most carefully no trace of a tumour could be found, but in the trigone there were four or five deeply congested patches about the size of peas, with slight ulceration on their surfaces, and in the surrounding mucous membrane a number of minute grey tubercles could be readily seen. These ulcers were scraped and iodoform powder applied. A large drainage-tube was left in. For a day or two there was a good deal of spasm of the bladder, but this soon passed off. The drainage was continued for six weeks. The bladder wound closed at the end of June. Up till the end of the year the patient had two very slight attacks of spasm and hæmaturia, but since that time he has had no further trouble and is now quite well.

CASE 2.—A man aged twenty-three years was admitted to King's College Hospital on Oct. 29th, 1891. There was a doubtful phthisical family history. He had what was termed "congestion of the lungs" four years ago and gonorrhœa three years ago. Soon after the attack of gonorrhœa he began to feel uneasiness and pain apparently about the base of the bladder; this lasted for a year and then improved, but he had never been quite free from the uneasiness, especially towards the end of micturition. For the last three months his bladder trouble had been getting worse, and he had once or twice passed a little blood towards the end of micturition; he had been losing flesh. On admission the patient's symptoms were as follows: some pain at the commencement of micturition and a great deal towards the end, the pain being referred to the bladder, perineum, and urethra; coughing set up aching about the bladder; micturition was frequent; and the urine contained a good deal of pus. There was no swelling or tenderness of the kidneys; the testicles and cords were normal. Per rectum the prostate was not enlarged; the vesiculæ seminales were distinctly felt, but were not hard. Just in front of the middle of the right vesicula and apparently in the wall of the bladder was a hard nodule about the size of a threepenny piece, which was exquisitely tender to the touch. On passing a sound no very great pain was felt till it touched the base of the bladder in front of this nodule, when it caused very great pain. With the cystoscope a bleeding, ragged area of considerable size was seen in the trigone; a few tubercle bacilli were found in the urine. On Nov. 24th Mr. Cheyne performed supra-pubic cystotomy and found in the trigone an irregular ulcer with ragged edges about the size of a shilling. On pressing on the nodule from the rectum a little curdy material appeared on the base of the ulcer. The surface was scraped, iodoform applied, and a drainage-tube inserted into the bladder. The patient had a good deal of spasm and pain in the bladder for some days, but these soon ceased. Injections of albumen obtained from tuberculin were also employed. The drainage of the bladder was kept up for six months, till, in fact, the nodule felt per rectum had almost disappeared and was quite free from tenderness. When discharged seventeen days later the wound was almost healed, and he could hold his urine for three hours and had none of the old symptoms. When seen about a year later he was well.

CASE 3.—A boy aged fourteen years was admitted to King's College Hospital on Nov. 14th, 1892. He had suppurating glands in the neck when quite a child. His mother died from phthisis. Four months before admission the patient began to have frequency of micturition and had a burning sensation on passing urine. The condition had been getting worse. On admission he complained of pain in the penis during and for about a minute after passing urine. There was no pain

in the intervals. He passed urine about twenty times during the twenty-four hours. Attempts to hold his urine caused much pain in the bladder. The urine was acid, with much pus; the sp. gr. was 1014. There was tenderness over the bladder both above the pubis and per rectum, the right side being much more tender than the left. There was no tenderness or swelling of either kidney, no disease of testicle, vesiculæ or prostate. With a sound the right side of the bladder was more tender than the left; no stone was felt. The temperature was 99.6° F. On Dec. 7th the bladder was opened above the pubis. There was a much congested, thickened, and somewhat warty patch on the right side of the trigone, but no actual ulceration was found. A large-sized drainage-tube was inserted into the bladder. In the beginning of January, 1893, the patient's temperature rose somewhat and afterwards assumed a hectic type, and about the end of that month tenderness over the left kidney was noted, and a good deal of pus was present in the urine; the kidney was also felt to be somewhat enlarged. This continued, and in the beginning of March the kidney was distinctly enlarged and the patient was losing ground. The tube was left out of the bladder on March 2nd. On March 13th the pelvis of the left kidney was opened; pus was found in it, and a drainage-tube was inserted. For a fortnight his condition improved, but he then began to get worse again, and accordingly on April 17th the left kidney was removed. On examination the kidney was found to be tuberculous. His condition rapidly improved, but the cystotomy wound was long in healing, and indeed, had not quite healed till the beginning of July, when the patient was discharged. At that time he had no pain in passing urine and could retain it for several hours; there were only a few pus corpuscles in the urine. His general health was very good.

CASE 4.—A man aged forty-nine years was admitted to King's College Hospital on April 13th, 1893. About six years previously the patient was in hospital with cystitis, which improved under treatment, but never got quite well. In August, 1892, his condition was such that he went into another hospital and was treated there for cystitis, but did not improve. He had passed a good deal of blood lately and had great pain in passing urine, and especially on trying to hold it. The patient stated that he had a burning pain in the perineum towards the end of micturition and lasting afterwards. He passed urine about every half-hour and frequently in bed while asleep. The urine was acid, with a good deal of pus and a trace of albumen. Tubercle bacilli were found in the urine in small numbers. Nothing was found in the kidneys or testicles. The patient was put to bed, and the bladder washed out daily with boracic lotion. No improvement followed, and on May 8th, 1893, the bladder was opened above the pubis. A thickened mass was at once come upon in the anterior wall, and a quantity of cheesy material was scraped away, leaving a raw place about the size of a florin on the anterior and upper part of the bladder; the rest of the organ appeared to be healthy. A large drainage-tube was inserted, but no iodoform was applied. The tube was left out on June 21st and the wound rapidly closed. He was discharged on June 28th, and was then able to retain his urine for three or four hours and had no pain in passing it. The urine was normal. The patient had greatly improved in his general condition.

Remarks by Mr. WATSON CHEYNE.—Little need be said as to the diagnosis of these cases; the symptoms were those of ulceration of the bladder, and in two of them (Cases 2 and 4) the tuberculous nature of this ulceration was at once settled by the discovery of tubercle bacilli in the urine. In the other two cases I failed to find tubercle bacilli, but such failure does not by any means imply the absence of tuberculosis. As is well known, in tuberculous disease of the urinary tract it is often difficult to demonstrate the bacilli. When they are few in number their discovery in the urinary deposit is an accident; a considerable number might be present and yet not happen to be in the minute portions examined; their discovery really implies the presence of large numbers. In the first case the eruption of tubercles on the mucous membrane of the bladder around the ulcers was, however, so typical that there was no difficulty in the diagnosis, which was agreed to by all who saw the operation. In Case 3 the diagnosis was rendered certain by the subsequent examination of the kidney. Three of these cases (Cases 1, 2 and 4) were certainly examples of primary tuberculosis of the bladder, there being complete absence of all signs of disease in any other

part of the genito-urinary tract both at the time and subsequently. I am inclined to regard Case 3 as also one of primary disease of the bladder, and to look on the affection of the left kidney as a subsequent occurrence, but the converse is quite possible, and there may have been originally a tuberculosis of the kidney which led to the bladder infection, but did not become acute till after the operation, when possibly some septic organisms spread up the ureter and lighted up the tuberculous deposit. The result of the treatment was most satisfactory in all the cases, and I believe that practically the sole curative agent in it is the rest given to the bladder by the suprapubic drainage. Scraping ulcers in the bladder is a very unsatisfactory performance, and one cannot hope to eradicate all the disease in this way. The bladder wall is a lax structure and one cannot scrape an ulcer in it, unless on the anterior wall as in my last case, with sufficient vigour to remove all the tuberculous material. Rubbing in iodoform is still more unsatisfactory. If iodoform has any anti-tuberculous action at all it is not a sudden one, and its application once for all, as in these cases, can have little or no effect. On the other hand, to place the part at rest is to act on the principles which are at the foundation of the treatment of tuberculous disease elsewhere, and this is at once done by the establishment of permanent drainage. It was because I held this view that I continued the drainage so long in these cases (from six weeks to six months), and I did not leave it off till I thought that the disease had been arrested.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.

CASE OF GASTROTOMY; REMOVAL OF A MASS OF HAIR WEIGHING 5 LB. 3 OZ. FROM THE STOMACH; RECOVERY.

(Under the care of Mr. PAUL SWAIN.)

IN THE LANCET of Jan. 9th, 1886, there is recorded by Mr. Knowsley Thornton a very remarkable case of removal of a mass of hair weighing 2 lb. from the stomach of a young woman aged eighteen. The patient recovered, and appended to the report Mr. Thornton has given an epitome of cases in which hair was found in the stomach. In only one other case, that of Dr. Schönborn of Königsberg, was an operation performed, and that with success, the mass of hair removed weighing 9 oz. or 10 oz. There are many post-mortem records. The most remarkable is one recorded by Russell in the *Medical Times* in 1869. A woman aged thirty-one died after an abortion, and there was found in her stomach a mass of hair weighing 4 lb. 7 oz. Since 1886 Mr. Swain can find only one case, and that is mentioned in THE LANCET of Nov. 24th, 1888. It is one recorded by Berg of Stockholm, who performed laparotomy on a woman twenty-six years of age and removed a mass of hair weighing about 30 oz. The patient made a rapid recovery. The case Mr. Swain relates is therefore the third on record, and is the most remarkable of the three as regards the weight of the hair removed.

A single young woman aged twenty was admitted into the South Devon and East Cornwall Hospital on March 15th, 1895, with a large abdominal tumour of which she professed to have been ignorant until a fortnight previously, when it was discovered by Dr. Hingston, who sent her into the hospital. Her history was as follows. As a child she had been healthy. Menstruation commenced at thirteen, but for the last year she had suffered from complete amenorrhœa. Five years previously she began to have attacks of vomiting, generally once daily and not always in relation to food; sometimes a week would elapse without sickness. It was for this condition that she first consulted Dr. Hingston two years previously. She had at one time a very fine head of somewhat coarse black hair which fell below her waist; but it is a fact to be noted that on three occasions during her illness she became quite bald. At the time of her admission she was a fairly well nourished girl with florid complexion, red lips, and quiet demeanour. The abdomen was largely distended by a tumour, which on palpation was found to be solid, well defined, and very movable laterally. It stretched obliquely across the abdomen from the left costal cartilages down into the pelvis, but the fingers could be passed round the lower border, between it and the pelvic cavity. It was continued up behind the left costal cartilages by a thick pedicle, apparently about ten or eleven inches in circumference. There was no tenderness on

pressure. The percussion note over the most prominent part of the tumour was slightly subresonant, and in some places there was a sense of crackling as if a bit of bowel were spread out over a solid tumour. The urine was normal. It is a curious fact that from the time of her admission until the day before the operation she was upon ordinary meat diet, which she took without discomfort, being only once sick. The diagnosis seemed to lie between a tumour of the omentum and a splenic enlargement. The constitutional condition of the patient precluded the latter idea. Moreover, on careful percussion over the splenic region it seemed to be possible to map out a normal spleen. On the 20th Mr. Swain opened the abdomen by a median incision about eight inches in length, the umbilicus being the central point. The stomach was immediately exposed and found to be enormously spread out, and on palpation air and fluid were displaced and the fingers came upon a solid tumour. Thinking that this was situated behind the stomach the great omentum was turned up and the whole mass lifted, when the posterior surface of the stomach was revealed. Whatever it was, therefore, it was within the stomach, which was replaced within the abdomen and well packed round with sponges. A small incision about two inches in length was then made through the stomach wall, and the contents were immediately found to be hair. The incision was then prolonged to six inches and the process of extraction commenced. At first small portions were removed with ordinary forceps, but this was soon given up, as the whole mass was welded together so firmly as to be almost impenetrable. At last an impression was made and an entrance effected into the centre with a very strong curved Volkmann's scoop. With this the interior of the mass was evacuated, the lower figure in the engraving representing the hair thus removed. By gentle manipulation, the stomach being carefully supported by the hands of an assistant, the whole mass was delivered, as represented in the upper engraving. The larger portion

lay in the pyloric end, whilst the other end was prolonged up towards the œsophagus, and was, in fact, the pedicle described above. The stomach evolved during the process of extraction was sickening. The mucous membrane at the pyloric end was studded over with circular raised patches of granulations, each about the size of a shilling; towards the cardiac extremity it was healthy. Immediately after the extraction the stomach contracted. It was well washed out with hot boracic solution and the opening closed with twenty-six Lembert's sutures. The sponges were then removed, and although a considerable

discharge of foul fluid had taken place it was found that the abdominal cavity had been well protected. The omentum was turned up over the incision in the stomach to afford extra protection, and the abdominal wound closed with silkworm gut sutures. The mass removed weighed 5 lb. 3 oz. The operation lasted an hour and a half, much time being expended in dislodging the hair. The patient rallied well from the operation. There was some little sickness, the vomited material being principally of a coffee-ground nature, from the blood extravasated during the operation. For two days she was fed with nutrient enemata only, and then small quantities of peptonised milk were given and the enemata lessened in number. The temperature never rose above 100·8° F. and reached that point only on one occasion. On the seventh day the silkworm gut sutures were removed. One near the centre of the wound had suppurated, and it was found, much to our disappointment, that a small gastric fistula was established. One of the Lembert's sutures was discharged through the opening. Feeding by the rectum was resumed, and in two or three days the fistula closed. The patient was discharged quite well on April 6th. It was never possible to extract much information from her. She acknowledged that she had indulged in the habit some time ago of eating her hair, but in very small quantities. The habit had never been noticed by her friends, and her mother could hardly be convinced of the fact until she was shown the mass of hair. The mass of hair has been sent to the Museum of the Royal College of Surgeons of England.

In our report of the case of carcinoma of the urethra and bladder, under Mr. Battle's care in St. Thomas's Hospital, which we printed last week, the name of the house surgeon was wrongly given. It was Mr. S. W. F. Richardson who had charge of the case, to Mr. Battle's complete and expressed satisfaction.

Medical Societies.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Fracture of the Extremities in Old People.—Intra-cranial Tumour.—Exhibition of Cases.

A MEETING of this society was held on June 7th, the President, Dr. R. BANNING, being in the chair.

Dr. ALDERSON related two cases of *Fracture of the Extremities in Old People*. The first case was a fracture of the neck of the humerus in a woman aged seventy-five years, in which union resulted at the end of seven weeks. In the other case a patient aged sixty-seven years sustained a fracture of the neck of the femur and recovered perfect use of her leg without any lameness. She had been treated by a long outside splint combined with weight extension, but convalescence was retarded by the formation of a bedsore.—Dr. ALDERSON also showed a boy aged thirteen years who one year previously had sustained a T-shaped fracture of the Lower End of his Left Humerus. The patient had been treated by wooden splints, and suffered from some stiffness of the elbow-joint after the splints were removed, but after passive movements under nitrous oxide gas he had regained almost perfect movement of his elbow.—Mr. LUNN referred to several cases of *Extra-capsular Fracture of the Neck of the Femur in old people due to indirect violence*, and showed two specimens. He advocated the treatment of such cases by plaster-of-Paris splints, which allowed of the patient getting up on crutches at the end of a week or two.—Mr. BIDWELL also urged the treatment of fractures of the femur by the immediate application of plaster-of-Paris splints. He also recommended that T-shaped fractures of the lower end of the humerus should be treated by a well-fitting plaster splint, which ought to be kept on for a month. If the fracture had been kept completely immobilised the movements of the elbow quickly returned without much trouble.—Mr. YEARSLEY also mentioned some cases of T-shaped fracture of the lower end of the humerus which had been treated by plaster-of-Paris splints, in all of which the subsequent movements of the elbow were excellent.

Mr. JULER read the notes of two cases of suspected Intra-cranial Tumour, one of which was demonstrated to the

society. The patients were women of the ages of eighteen and thirty-eight years respectively, and had come under observation on account of severe double optic neuritis. In one case the swelling of the papilla had subsided into post-neuritic atrophy, with improvement of vision. In the other a severe choked disc existed with complete blindness. Vomiting and severe headache had existed at different times in each case. These two symptoms, however, were almost invariable accompaniments of any severe optic neuritis. Mr. Juler was of opinion that, few as the symptoms were which pointed to intra-cranial mischief, they were sufficient to guide to a diagnosis, for in one case fits, failure of memory, and weakening of the lower extremities existed, while in the other periodical attacks of unconsciousness occurred. He considered that both cases belonged to that class which Dr. Hughlings Jackson has called optic neuritis with non-localising symptoms.—Mr. LUNN mentioned a case of double optic neuritis in which a cerebellar tumour was found and successfully removed. He also referred to a case of cerebral tumour which proved fatal after operation.

Mr. MAYO COLLIER showed a youth aged seventeen years on whom he had operated for Hallux Rigidus. Treatment by rest, tonics, and frictions was tried first without producing any effect, so the head of the metatarsal bone of the great toe was excised. The usual pressure caries was present on the under surface between the sesamoid bones and the head of the metatarsal bone. Locomotion was now completely restored without any changes in the functions or appearance of the foot.—Mr. BIDWELL considered that most of the cases of hallux rigidus could be relieved by forced extension under chloroform, after which the toe should be kept in a state of over-extension, by means of a plaster-of-Paris splint, for fourteen days.—Mr. YEARSLEY remarked on the combination of this condition with flatfoot.

Mr. MAYO COLLIER also showed a man aged thirty-two years who had been the victim of severe Trigeminal Neuralgia for over four years. On examination of the nose several mucous polypi, together with a piece of dead bone, were discovered. These were removed and the patient had not suffered any more from neuralgia. Mr. Collier pointed out that since the whole of the interior of the nasal cavities was supplied by nerve branches springing from the nasal ganglion of the second division of the fifth nerve irritation of the nose was almost the most frequent cause of trigeminal neuralgia.—Mr. LAKE drew attention to the more common situation of neuralgia in nasal cases and said that he was interested in the question of necrosis without even a suspicion of specific history.

Mr. KEETLEY showed two cases of Compound Comminuted Fracture of the Tibia and Fibula which had been treated by pegging and wiring of the fragments. He insisted on the necessity of keeping all the fragments even if several pieces of wire had to be inserted.

Mr. BIDWELL showed a man aged seventy-four years suffering from a Rodent Ulcer on the outer side of the left thigh. It had existed for four years and was of the size of a teacup. A portion had been removed for microscopical examination and was found to be typical of rodent ulcer. Mr. Bidwell recommended free excision, combined with immediate Thiersch's grafting.—Mr. BIDWELL also showed a boy aged seventeen years who suffered from a Warty Growth below the Jaw. This had arisen round the sinus formed from a carious tooth which had existed for five years. He considered that the warty growth was due to the continual irritation of the purulent discharge.

EDINBURGH OBSTETRICAL SOCIETY.

Chorea Gravidarum.—The Blood of the Newly Born Child.

A MEETING of this society was held on June 12th, Dr. A. H. FREELAND BARBOUR, President, being in the chair.

Dr. JAMES RITCHIE showed two Supernumerary Digits removed from a child three days after birth. Both grew from the ulnar side of the first phalanx of the little finger on each hand. The digits consisted of two phalanges and had small nails on them.

Dr. R. C. BUIST read a paper on Chorea Gravidarum in which he gave the histories of some cases as yet unreported and also a careful digest of 255 cases where this complication of pregnancy existed. In one case the movements were noticed to become less during the pain and more exaggerated after it had passed off. The child had two fits after birth. Two cases had for their cause an unruptured hymen and a polypus of the urethra. Both conditions were the source of

much pain, and on being treated the chorea accompanying the pregnancy disappeared. Of the 255 cases 66 had suffered from chorea previously to pregnancy, and 23 had had no previous attack; in 6 cases the chorea appeared at the onset of pregnancy. As regards age, the statistics show that it becomes increasingly less common after twenty-four years. With reference to the period of pregnancy when the symptoms began, it was found that 108 cases commenced in the first three months, 70 during the second three months, 25 in the last trimester, and 15 after labour. There were 45 fatal cases in 255 pregnancies where this complication existed, giving a death-rate of over 17·5 per cent. This is probably much in excess of the actual mortality, as minor cases are not reported and some of these deaths are due to other complications, eclampsia, albuminuria, &c. Induced delivery was effected in 21 cases, with fatal results in 9 cases. A considerable number improved after operation. The general prognosis depended partly on the degree of the symptoms, as the less severe the chorea the more hopeful was the recovery; 61 cases recovered before the onset of labour, 91 after the birth, and 7 became chronic. It was interesting to note that the patient may escape entirely in subsequent pregnancies. Appended to this paper was a table analysing the 255 cases—Professor SIMPSON remarked on the high mortality attending interference with the course of pregnancy, but believed this was due to delay in operating when serious symptoms were present, and where induction was only performed as a last resort.

A paper was read on some observations on the Blood of the Newly Born Child by Dr. GEORGE ELDER and Dr. ROBERT HUTCHISON. The blood of the child was obtained from the umbilical cord on tying it and thus the results show its condition immediately on birth; other observers have noted its composition after six to eight hours. The blood of the mother was obtained from the lobe of the ear. In the child the red corpuscles numbered on an average 5,346 000 per c.mm.; and thus from 350 000 to 500 000 more per c.mm. than in adults. During the first day or two they seem rapidly to increase, and afterwards decrease gradually. There is no difference in size or shape from those of adults. Nucleated red blood-corpuscles are present at birth in considerable numbers, but these vary greatly; on the second or third day they only saw a few and by the fifth day none could be observed. In the mother the red corpuscles in 16 cases varied from 2 to 5 millions per c.mm., and were thus below the normal average. The child had always considerably more than the mother, nearly always to the extent of 1 million per c.mm. It was thus found in these maternity cases that *anæmia* was the prevailing condition in the mother, and *plethora* in the child. In estimating the hæmoglobin the blood of the child was found to contain 95 to 115 per cent. of the normal average, so that each corpuscle was richer in hæmoglobin in the child than in the adult. In the mother the hæmoglobin was found to vary from 60 to 83 per cent., only two-thirds of the richness of the child's blood. The white corpuscles in the child were on an average 17 800 per c.mm. and thus roughly twice as much as in the ordinary adult. These observations gave the proportion of 1 white to 298 red corpuscles in the child, the ordinary proportion being about 1 to 500 in the adult. The number increased shortly after birth and then decreased proportionately with the red. The white corpuscles in the mother in 11 cases were found to have an average of 14 000 per c.mm., this being much higher than in the normal adult. In some cases the number was equal to that of her child. A few days after labour there was a marked decrease in their number, at least in those who nursed their children. From these observations it was very evident that there is no mixing of the maternal and foetal blood. Possibly the increase of hæmoglobin and of the number of red blood-corpuscles compensates for the absence of respiration. Dr. Milne Murray had mentioned in his investigations by spectrum analysis of foetal blood that he had found that in order to get a reduced spectrum he required to add seven times as much reducing agent as was necessary to reduce the mother's blood. The foetal blood was much richer in hæmoglobin than the mother's, but this showed also that the hæmoglobin was more chemically active, so that in the placenta on the maternal side the oxygen was loosely held, while on the foetal side there was very great attraction for it.—Dr. JAMES RITCHIE remarked that these observations showed that the quality of blood in the child was regulated by the quality in the mother, and it was necessary for them as practitioners to promote the health of the mother during pregnancy.

Reviews and Notices of Books.

La Thérapeutique des Tissus: Compendium des Médications par les Extraits d'Organes animaux Par le Dr. M. BRA. Paris: J. Rothschild, Éditeur. 1895. (*Tissue Therapeutics: A Compendium of Treatment by Organic Animal Extracts.* By Dr. M. BRA. Paris: J. Rothschild. 1895.)

THE alternative title of this work—"La Méthode Brown-Séquard: Traité d'Histothérapie"—indicates its scope and purpose. The author, a pupil of the late eminent physiologist, has fulfilled a task to which Professor Brown-Séquard intended to have devoted himself had his life been longer spared. This task was to collate the facts and observations relating to the new departure in therapeutics which he introduced in a somewhat startling and dramatic way by his account to the Société de Biologie of his personal experiences of the tonic effect of an orchitic extract injected hypodermically. It is pathetic to read the text of this first communication of his on the subject, and to hear the aged Professor relate how his physical and mental vigour were restored in a surprising manner by this simple expedient, and yet it is impossible not to admire the enthusiasm with which he advocated a method that almost promised to annul and arrest the natural decay of old age. Arguing from the marked physical and moral effects ensuing on castration in early life, and also on the results of inordinate exercise of the sexual glands, Professor Brown-Séquard inferred that these glands, above all others, supply the blood with principles which furnish energy to the nervous system and also probably to the muscular. He had, he said, long thought that some part of senile debility was to be explained by the withdrawal of their stimulating influence, and so long ago as 1875 he instituted experiments to test the value of his hypothesis. The issue of his researches is well known, and it has come to pass that sterilised extracts of the testes of young and vigorous animals have been prepared and prescribed for administration, mainly by the hypodermic method, for the treatment of neurasthenia, and even of organic diseases of the nervous system, besides a variety of affections such as tuberculosis, cancer, diabetes, and skin diseases. It is astonishing to find from the records here collected how wide has been the field on which this orchitic extract has been tried, and it is difficult to refrain from entering a grave protest at the irrational and extravagant claims that are advanced for its use. If but a tithe of the successes here described could be really substantiated we should possess in this animal extract not merely the most potent of remedies but one which ought to be universally prescribed. But, unfortunately, experience teaches that remedies vaunted the most loudly, and especially those which are ranked as panaceas, never fulfil the expectations of their advocates when tested by an impartial tribunal. The other animal organs which have been impressed into service of this kind of therapeutics comprise the ovaries, the cortical matter of the brain, the thyroid, the heart, the pancreas, the liver, the adrenals, muscle, the kidneys, the lungs, bone marrow, and the spleen—a list which calls to mind the contents of the witches' caldron, and the warranty for which is, with one striking exception, based on the most slender of grounds. Indeed, the author of this compendium himself points out that many of these extracts have not come up to anticipation. The ovarian extract, for example, has never gained much favour; "cardine," "nephrine," and "pneumine" are of little value in restoring the functions of a damaged heart, kidney, or lung. Nor can much be said in proof of the efficacy of extract of pancreas in diabetes, or of that of the liver in biliary intoxication. Undoubtedly

the singular efficacy of the thyroid treatment of myxœdema has done much to excite hopes of a similar good resulting from the use of extracts of other organs in affections where the functions of such organs are in abeyance; but it may be permitted to us to point out that the really positive results hitherto obtained have been mostly in connexion with glands that subserve some purpose in general nutrition, and that therefore there is more to be anticipated from the use of adrenal extract in Addison's disease, and of bone marrow in idiopathic anæmia, than from the use of "cerebrine" in mental disorder or of "nephrene" in Bright's disease. Whether it is quite legitimate to rank thyroid medication as one of the gains of the new principle introduced by Professor Brown-Séquard may perhaps be questioned, since its employment in myxœdema was strictly based on deductive reasoning from the known phenomena of cachexia strumipriva.

We confess our inability to assume any other than a sceptical attitude towards most of the medicaments here so exhaustively treated; but in spite of our belief that in a few years most of them will have fallen into oblivion we fully recognise the ability with which this book has been compiled. More than that, we think it is a book which needed to be written. It contains in the form most suitable for reference every detail regarding the preparation, physiological action, and therapeutical application of animal organic extracts, and the facts so gathered are marshalled with marked skill and candour. It concludes with an interesting summary of the "internal secretions," classified under the two heads of (1) those which maintain the composition of the internal medium, as the "secretion" of the spleen, of bone marrow, of vascular endothelia, and of the generative glands, and (2) those which protect the organism against self-intoxication (chemically acting glands), as the "internal secretion" of the liver, of the suprarenal capsules, of the pancreas, of the kidney, or of the thyroid gland. And the following are given as evidences of the insufficiency of such internal secretions: (a) of generative glands—diminution of the general activity of the nervous system; (b) of the pancreas—glycosuria, diabetes; (c) of the liver—appearance of morbid phenomena coexisting with icterus; (d) of the kidney—uræmia; (e) of the adrenals—asthenia, the chief symptom of Addison's disease; and (f) of the thyroid—myxœdema, cretinism. The work is one which should be read as indicating a remarkable phase in physiological theories; and in testimony of the cosmopolitan interest taken in the subject reference may be made to the letters prefixed to the volume from Dr. Constantin Paul, Professor Ewald, Dr. Byrom Bramwell, Dr. Emminghaus, and Professor Mendel.

Annals of Ophthalmology and Otolaryngology. Published by James Parker, St. Louis, Mo. Vol. IV., No. 2. 1895.

THIS part contains a considerable number of articles, some of which are of much interest. Dr. F. C. Hotz of Chicago discusses and opposes the views of Dr. Savage, who maintains that the oblique muscles are brought into action for the improvement of vision in cases of oblique astigmatism. Dr. F. B. Eaton of Portland draws attention to the discrepancy that exists between the laws of parallel ocular motion, as formulated by Listing and Helmholtz, and their statement and interpretation in text-books, and suggests various modifications of the views generally accepted. Dr. M. W. Zimmerman of Philadelphia contributes an article on Hypermetropia of High Degree, and points out, *inter alia*, that astigmatism is present in about 50 per cent. of hypermetropes of high degree, but decreases as the error becomes higher, and also that the principal complication is convergent strabismus, which is more frequent with lower degrees of the error. Dr. Chalmer Prentice of Chicago proposes a

new operation for the advancement of the recti, in which two small curved aluminium plates are employed over which the ligatures are tied. For the details of the operation we must refer our readers to the original. Dr. Maurice F. Pilgrim of Carbondale propounds the question, "Is Glaucoma curable without Operation?" and answers it in the affirmative, giving illustrative cases. Dr. Wendell Reber of Pottsville asks, "Is the Physiognomy of the Fundus Oculi in Epilepsy characteristic?" and from observations that he has had the opportunity of making on a large number of epileptics has arrived at the conclusion that in typical cases the optic disc is too abundantly supplied with capillaries, whilst it is grey in its deeper portions; that the scleral ring is sharply cut on the temporal side, that the retinal fibre layer is increased in thickness, especially above and below the disc, and that the retinal lymph sheaths are distended and opaque. Dr. W. Franklin Coleman of Chicago treats at some length the subject of Amblyopia ex Anopsia, which he holds may occur, basing his argument on the improvement of vision observed in strabismic eyes after operation. Dr. Charles Stedman Brill of New York records cases of Purulent Inflammation of the Eyeball and Orbital Tissue and Paralysis of the Ocular Muscles as possible Complications or Sequelæ of Influenza. Dr. Robert Saunders of Philadelphia describes an anomalous case of Interstitial Keratitis. Lastly, Dr. Frank W. Ring contributes a case of a thorn which remained buried in the sclera without occasioning inconvenience for thirteen years, when it worked its way out. The second part of the volume is devoted to Otolaryngology, and is chiefly occupied with a paper by Dr. M. A. Goldstein of St. Louis on Exfoliation of the Cochlea, Vestibule and Semicircular Canals; an account of an unusual case of Aural Deformity and operation thereupon, by Dr. J. Hollinger of Chicago; and an account by Dr. David N. Dennis of Erie of the Injector of Delstanché with Modified Middle-ear Lip.

The Schott Methods of the Treatment of Chronic Diseases of the Heart. Illustrated. By W. BESLY THORNE, M.D., M.R.C.P. London: J. & A. Churchill. 1895.

IN six short and very readable chapters the author gives an interesting account of the methods used in the treatment of heart disease at Nauheim. After giving an account of the waters of Nauheim and showing that effervescent saline baths may be used elsewhere, the effects of such bathing upon the pulse-rate and circulation generally are illustrated, the usual effect being a diminution of its frequency and increase in its force. Sphygmograms in proof are given. We may mention in passing that No. 6 of these shows that pulse pressure may be increased at the same time as pulse frequency. The pulse-rate of this illustration is not given, and our inference is based upon the sphygmogram. The therapeutic movements, which are conveniently and copiously illustrated, also result in retardation and increased force of the pulse. Their "immediate" effect is stated to be to slow the pulse. The sphygmograms given, however, show that the immediate effect is to quicken it somewhat, as is the case with all forms of exercise, although doubtless the result of such quickening by unloading the heart is the retardation usually observed. Incidental reference is made to Oertel's system of graduated mountain climbing, which is very properly considered advisable only after cardiac force has in great measure been regained. The author, however, omits to state that Oertel expressly advises flat walking—that is, gentle exercise—as a preliminary to carefully ascending heights. As is well known, Stokes of Dublin was the first to recommend this method of treatment in appropriate cases. All cases are said to be suitable for the Nauheim Kur except those in which there is advanced degeneration of the myocardium or considerable sclerosis of the vessels. In the sixth chapter Dr. Besly Thorne relates ten cases which

were successfully treated. The majority of these were cases of cardiac dilatation, and a minority presented evidence, not quite conclusive in our opinion, of organic valvular disease. We make no doubt, however, that many cases of organic valvular disease benefit under the carefully regulated exercises described. If we have avoided the language of enthusiasm in our remarks it is because of our conviction that in no sphere is such less appropriate than in that of therapeutics, a subject which scientific medicine must ever approach with the calm and judicial mind which regards with a healthy scepticism the panacea. The chronicle of failure is always an important adjunct to therapeutic works, for such unfortunately must occur under any system.

LIBRARY TABLE.

Diättherapie für Aerzte und Studierende. Von Dr. FRIEDRICH SCHILLING. Wiesbaden: Verlag von J. F. Bergmann. 1895. (*Dietetic Therapeutics for Practitioners and Students.* By Dr. FRIEDRICH SCHILLING. Wiesbaden: J. F. Bergmann. 1895.) — Dr. Schilling's little manual of Dietetic Therapeutics is likely to be useful to medical men and students, though it contains little that is not to be found in ordinary books on the practice of medicine. He does not advance any startling novelties, and although a few of the dishes and meals mentioned are more suited to German customs than to those prevalent in this country the general principles which guide the rules as to diet are those commonly acted upon by English medical men. Thus, after a confinement the patient is recommended to be kept on the diet suited for acute febrile cases until the fourth day, when meat may be allowed. The old custom of starving the woman for a week with the mistaken object of preventing "milk fever" is only mentioned to be condemned. In diabetes moderation is recommended in enforcing a purely proteid diet. Several pages are occupied in discussing the many forms of treatment that have been recommended for corpulency, and the author's remarks on this subject will well repay perusal.

The Disorders of Speech. By JOHN WYLLIE, M.D., F.R.C.P. Edin. Edinburgh: Oliver and Boyd. 1894.—It is not easy to speak of this book in terms which would do it justice. It is, in the first place, one of the most complete treatises on disorders of speech in any language, and it is characterised by admirable arrangement and lucidity of expression. It is divided into three parts, the first dealing with functional disorders of the vocal mechanism, of which stammering is the most important and also the most interesting; the second with the development of speech and the developmental derangements; and the third with speech in its relation to the diseases of the nervous system. Such a plan is obviously comprehensive, and it may be said at once that the details of the plan are carried out in a manner which cannot fail to impress and to satisfy the most exacting critic. In the first part the view is definitely expressed—and, in our opinion, abundantly justified—that whispering is not purely an oral and lingual matter, but that the laryngeal mechanism is necessary for its production. Anyone who carefully considers what Dr. Wyllie has written on this subject can scarcely fail to be convinced of the correctness of his view. In this section the statement is made that abductor paralysis is exceedingly rare, much rarer than adductor, but this we would venture to call in question. No doubt abductor paralysis is not very common, but we cannot help thinking that the author must have overlooked the considerable frequency with which it is met with in cases of tabes dorsalis, especially in those cases in which laryngeal crises occur. The second part is very interesting, and the third is full of practical interest, perhaps erring a little on the side of being rather too definite in regard to the different forms of aphasia. But the book as a whole is, as we have

already said, admirable, and Dr. Wyllie is to be congratulated on the interest—the outcome evidently of intimate knowledge—which he has infused into the work, and the medical profession of this country on a most valuable scientific addition to its means of grappling with a very difficult, if most interesting, class of disorders.

New Inventions.

THE "ARIA" PATENT SAFETY LAMP.

WHETHER or no it is desirable that the flashing point of burning oils should be altered, so as to secure greater safety in their use, is a question which will shortly be decided probably by a Select Committee. The increasing number of accidents, accompanied in many instances by more than one fatality, points at any rate to the necessity of some increased precautions being enforced by the Legislature either in the direction of providing the public with safe oils or else by insisting upon the use of safe lamps. At the present time the heavy oils which might serve for lighting purposes are not very easy to procure, while there is some difficulty in getting them to burn as satisfactorily as the lighter petroleum. It is obvious, however, that provided the lamp can be obtained which will burn the heavier oils—that is, those oils from which the highly inflammable and highly volatile oils have been removed—with as good results as the lighter kinds at present supplied, the first difficulty, namely, that of procuring "mineral colza oil" easily and at a cheap rate, will soon disappear. The "Aria" lamp is constructed to burn both oils, but security is made doubly secure by employing an oil of as high a flashing point as 250° F. and of specific gravity 0.827, which it burns perfectly well and freely, giving a brilliant steady flame of high candle power. As will be seen in the accompanying illustration, it consists of two reservoirs—a large one like a hollow collar round the

centre of the lamp holding the bulk of the oil to be consumed, and a smaller or secondary open reservoir containing the wick. The advantages of this arrangement are that the air is constantly playing around the secondary reservoir, which keeps it quite cool, so that there is no heat conducted to the large reservoir at all; charring of the wick is avoided, because, although it is immersed in a small quantity of oil, yet obviously the level of the oil is maintained in the wick tube by the pressure of the oil in the large reservoir outside; and lastly, if the lamp is by any chance upset the flame is immediately extinguished. In the latter case the bulk of the oil is retained in the larger reservoir, which being anchor-shaped only in

the reversed position, contains and traps the oil, so to speak, in each limb. Besides this the air is free to rush in so rapidly as to put out the flame. Several experiments which we made convinced us of the safety of this lamp. Even the ordinary petroleum oil of comparatively low flash-point, such as that at present supplied for ordinary use, may be safely burned in this lamp, as the reservoir is kept remarkably cool by being freely surrounded with air. We also found that the flame is extinguished by the upsetting of the lamp. Thus on turning the lamp smartly upside down when fully alight the flame was instantly extinguished by the inrush of air with the production of a trifling volume of smoke and vapour. A feature of additional importance in this lamp is that a flame of full size may be obtained without raising the upper surface of the wick more than one-sixteenth of an inch above the top of the wick tube, the depth of charring consequently being very slight. The most important advantage, however, of the "Aria" lamp is that it will burn oils from which the inflammable or volatile portions have been removed, giving a steady, brilliant flame, emitting no smell, and absolutely free from any liability to explode or ignite even when upset. Under these circumstances the use of this lamp would amply compensate for any difficulty experienced in procuring those oils which at present are not in great demand, on account of the want, hitherto, of a lamp which would burn them with good results. This want, we venture to think, has now been satisfactorily supplied. The "Aria" lamp may be seen in operation at the offices of the Cheap Wood Company, 72, Bishopsgate-street, E.C.

A NEW ACCOUCHEMENT SHEET.

UNDER the name of "cusheet," Mr. John Milne, the Antiseptic Dressings Factory, Ladywell, London, S.E., has designed a new accouchement and operation sheet, which is well adapted to the purposes it is intended to serve. The sheet or pad is composed of cellulose, which is sterilised before being placed in an outer covering rendered antiseptic by treatment with corrosive sublimate. The cellulose is a powerful absorbent, is very soft, and the "cusheet" can be put to other uses besides those mentioned. Any size and thickness can be made to order, but the two feet square size is a convenient one, and the price—1s. 6d. each—is not too high to permit of the sheets being burnt, as they should be, after use.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary meeting of the Council was held on the 9th inst., the President, Mr. Christopher Heath, being in the chair.

A report, dated June 10th, from the Committee of Management of the Examining Board in England was approved and adopted. The committee made the following recommendations: (1) that the course of clinical instruction on diseases of women at the Southern Hospital, Manchester, given by Dr. W. J. Sinclair, be recognised as fulfilling the requirements of clause (d), paragraph 7, section I. of the regulations, so long as he shall hold the Professorship of Obstetrics and Gynaecology at Owens College, Manchester; and (2) that on the application of the Dean of Charing-cross Hospital Medical School the course of clinical demonstrations in lunacy, given by Dr. Percy Smith at Bethlem Hospital, be recognised so long as he shall hold the Lectureship in Psychological Medicine at Charing-cross Hospital Medical School.

A report, dated June 7th, from the Laboratories Committee was approved and adopted. The report dealt with the work in diphtheria for the Metropolitan Asylums Board,

and was as follows: "Examination of material for diagnosis.—Since March 11th 2180 specimens have been examined and reported upon. The Metropolitan Asylums Board have requested the committee to continue the work for the further period of six months, and the committee have agreed to do so subject to a slightly increased payment by the Asylums Board for the extra work involved by the number of cases per day being in excess of the estimate. It was anticipated that the daily average number of cases would not exceed twenty, whereas the cases examined are rarely below, and very frequently greatly in excess of, that number."

The director has undertaken, in conjunction with the medical superintendents of the hospitals, to report fully to the Metropolitan Asylums Board on the cases examined.

The Council decided that the bust of the late Sir Richard Owen, K.C.B., to be executed by Mr. Alfred Gilbert, R.A., should be of bronze.

A report dated May 17th from the President and Vice-Presidents on section 16 of the by-laws was approved and adopted; the Secretary of State had suggested that the first three clauses of this section should be condensed into a single paragraph as follows: 1. If any Fellow or Member of the College shall after due inquiry be judged by the Council to have been guilty of disgraceful conduct in any professional respect, he shall be liable to removal by resolution of the Council from being a Fellow and Member or Member of the College.

The Council abrogated and annulled the old by-laws and ordained the new by-laws and signed them. It was moved and adopted that section 16 of the by-laws as approved by the Home Secretary be read to the meeting of Fellows on the 4th prox., and that, inasmuch as the by-laws have now been sanctioned, the correspondence of the Society of Members and of the Council with the Home Secretary on the subject be not now reported to the meeting.

A letter was read from Mr. Charles S. Tomes resigning his appointment as a member of the Board of Examiners in Dental Surgery. The resignation was accepted, and the President stated that the vacancy thus occasioned, and also the vacancy caused by the expiration of the period of office of Mr. Ashley Wm. Barrett, would be filled at the quarterly meeting of the Council on July 11th. A letter of the 10th inst. was read from Mr. Thomas Bryant, reporting the proceedings of the General Medical Council. The thanks of the Council were accorded to Mr. Bryant for his services as representative of the College on the General Medical Council.

A letter of May 10th was read from Dr. Liveing, reporting the following proceedings of the Royal College of Physicians of London on May 9th—viz.: 1. The adoption of the report, dated April 22nd, 1895, of the Committee of Management. 2. The adoption of a resolution inviting the Royal College of Surgeons to appoint delegates to confer with a like number from the Royal College of Physicians as to what points should be urged or suggestions made before the proposed Statutory Commission for giving effect to the report of the Gresham University Commission, and to prepare a joint report to the two Colleges. 3. The appointment of the President, the Registrar, Dr. Norman Moore, and Dr. Allchin as delegates.

The Council, in pursuance of the invitation of the Royal College of Physicians, proceeded to appoint as the four delegates of the Royal College of Surgeons the President, Mr. Howse, Mr. Rivington, and Mr. Morris.

WIGAN MEDICAL SOCIETY.—An ordinary meeting of this society was held on June 13th, the President, Mr. Wm. Mitchell Moorcroft, being in the chair.—Mr. Brady showed a case of Compound Fracture of the Lower End of the Femur, which he had treated on a MacIntyre splint in a poor cottage with a very good result.—A paper on Alcoholic Insanity was read by Mr. Street, medical superintendent of Haydock Lodge Retreat. The subject was dealt with in an exhaustive and interesting manner. A discussion followed, when Mr. Jones, Mr. Blair, Mr. Brady, Dr. Rees, Mr. Lowe, Mr. Molyneux, Dr. Benson, and the President took part, the President dealing with the treatment of inebriates in licensed houses, and pointing out that the previous Acts require amending very considerably before the subjects can be efficiently dealt with. A hearty vote of thanks was accorded Mr. Street for his paper.

THE LANCET.

LONDON: SATURDAY, JUNE 22, 1895.

FOR the five vacant seats on the Council of the Royal College of Surgeons of England, to be filled at the election on July 4th, there is an ample supply of excellent candidates with evenly balanced claims and all on their own merits worthy of the suffrages of the electors and of a place on the Council. All may be said to have obtained in their respective spheres more or less distinction as practitioners and authors, and all have reached a position in the profession which justifies them in coming forward on the present occasion. If one may appear more brilliant another may be more solid; if one attracts us by his versatility another commends himself by his modesty and judgment; one may possess the energy and impetuosity of comparative youth, another the light of experience and the stability of age. Hence for many of the Fellows the task of selection must be difficult, and it would be so to ourselves if we had not some definite principles to guide us in our choice. To surgical repute, success in practice, and the pen of a ready writer, great weight is justly attached; but they ought not to be allowed to dominate the election in the present state of the relations of the College to the profession, or to override considerations which vitally affect the interests of the constituency. Old associations, the rivalry of schools, personal friendships and preferences play so considerable a part in every election that there is the more need for the display of that public spirit on the part of independent electors which makes everything subordinate to the welfare of the College and of the profession. From this point of view it is that known liberality of opinions and a determination to support such measures as will bring the Council into nearer touch and more harmonious relations with the constituency assume increased importance as qualifications for a seat on the Council at the present time, and such qualifications some of the candidates are known to possess.

To seniority in the Fellowship some regard should be paid. The election of a junior candidate over the heads of seniors may be necessary and even justifiable where principles are at stake, and in recent years there have been one or two notable instances of this. Under ordinary circumstances, however, and with otherwise equal claims, a senior candidate who would be a desirable addition to the Council is entitled to the preference. The sudden elevation of a junior candidate, whether in the appointment of an examiner or in the election to the Council, is rarely justified by the result and inflicts considerable hardship upon the senior candidate. In the present instance the candidates who are seniors to the others—viz., Mr. WILLETT, Dr. WARD COUSINS, and Mr. A. T. NORTON—happen to be the candidates with whose views the constituency is best acquainted and who are promoters of that policy of progress and reform with which THE LANCET has ever been identified. Without professing a complete agreement with all the details of the changes which the Association of Fellows advocates, and which, of course,

discussion both in the Council and outside it may modify, we gladly recognise once more the claims which the candidates supported by the Association have upon the favourable consideration of the constituency. Mr. ALFRED WILLETT (Fellow, 1862; Member, 1859) has served one full term of eight years on the Council, and is now one of the Vice-Presidents of the College. He has been a loyal supporter of the movement for conferring upon the Fellows a more influential voice in the affairs of the College. His re-election must be practically assured, but his faithful services ought to be acknowledged by his return at the head of the poll. Dr. WARD COUSINS (Fellow, 1860; Member, 1856) is well known as a frequent and original contributor to surgical science, as a picturesque speaker, and as possessing an aptitude for business as well as administrative ability. He would represent especially the southern section of the provinces, at present unrepresented, and would take the place of the late Mr. SIBLEY in his special acquaintance with the needs of the general practitioner. Mr. A. T. NORTON (Fellow, 1867; Member, 1862) we supported in 1893, when he ran so close a race with Mr. HENRY MORRIS and only failed to succeed by two or three votes. He has continued to be a staunch supporter of the cause of the Fellows, and was the chief exponent of the views of the Association of Fellows on the deputation which was received at the College last week by a committee of the Council. His success at the election would be a material assistance to the cause of reform. Mr. ALFRED COOPER (Fellow, 1870; Member, 1861) has attained a recognised position as a specialist, but has not taken any active part of late years in the politics of the profession, so that the constituency has not enjoyed much opportunity of becoming acquainted with his views on current questions. Mr. ANDERSON (Fellow, 1869; Member, 1867), Mr. J. N. C. DAVIES-COLLEY (Fellow, 1870; Member, 1863), and Mr. H. W. PAGE (Fellow, 1871; Member, 1869) are able surgeons and estimable and cultivated members of the profession. All three, however, are on the Court of Examiners, which already possesses four representatives on the Council. There are some who consider that membership of the Court of Examiners is a recommendation for a seat on the Council; but, as may be gathered from our remarks last week, we do not share this view. The duties of members of the Court of Examiners are very exacting, and during the examinations, which are frequent, leave little time for anything else. Moreover, experience has shown that the combination of the two offices of examiner and councillor has not been beneficial to progress at the College. Four members of the Court of Examiners are already members of the Council, and it would certainly be inexpedient to increase the proportion over one-half. There is so little to choose between the three that it is almost invidious to make a selection. Last year, however, when all three stood, we supported Mr. DAVIES-COLLEY on the ground that he was believed to be favourable to a new Charter for the College, and we see no reason to withdraw from this selection. Mr. H. T. BUTLIN (Fellow, 1871; Member, 1867) is an unexceptionable candidate with liberal proclivities. He is an excellent speaker, and his surgical work and attainments are too well known to need recapitulation. The same remark applies to Mr. TENNES (Fellow, 1878; Member,

1875), who, though last, is certainly not least. His capacity for work of an encyclopædic character rivals that of Mr. HUTCHINSON, who probably first inspired him as he has inspired many others at the London Hospital and elsewhere. Mr. TREVES is considerably junior to the other candidates, and it would not be, perhaps, the same hardship if his election were postponed as might be the case with regard to one or two other desirable candidates on the list.

We make these few remarks upon the candidates to show that our sympathies remain, as they ever have been, enlisted in the cause of good government at the College. It is our great desire to see cordial and harmonious relations established between the Council of the College and the Fellows and Members, in order that the status of the profession may be elevated and its organisation perfected. The Fellows will be able to judge for themselves who are the men best qualified to complete the work which has been begun, and we commend the respective claims of the candidates to their careful and earnest consideration. For our own part, we should select the five candidates to be voted for from the following list—viz., Mr. WILLETT, Dr. WARD COUSINS, Mr. NORTON, Mr. DAVIES-COLLEY, Mr. BUTLIN, and Mr. TREVES.

We have already noticed the reports for 1894 of the Statistical Committee of the Metropolitan Asylums Board, but we reserved the reports of the medical superintendents of the several infectious hospitals of the Board for separate notice. We have never failed to regard these reports with interest, and to derive great instruction from them. Never before or elsewhere in the history of the world have members of our profession had the chance of seeing and treating on such a scale the great groups of infectious disease which constitute so large a proportion of the sickness of the people. The number of cases of infectious disease notified last year was 34,203. No less than 62·9 per cent. of the cases of scarlet fever which are notified, 32·8 per cent. of those of diphtheria, and 15·9 per cent. of those of enteric fever find their way into these hospitals. The very least we can do in regard to such a mass of disease, taken, as it were, out of the hands of the profession outside, is to study the lessons taught us by the responsible medical officers who have charge of it. Our readers must anticipate with much interest the report of the medical superintendents on the effects of the antitoxic serum in the treatment of diphtheria, with which the hospitals of the Asylums Board are abundantly supplied through the kindness of the Council of the British Institute of Preventive Medicine. All the officers make allusion to this subject. We cannot too highly praise the caution and reserve with which the medical superintendents speak. While doing so in a tone of hope, they cordially realise the gravity of the question for the answer to which they have almost a monopoly of material. We trust that no pressure will be brought to bear on them to deliver a premature opinion. They will do much more for medical science by deliberation and delay and by applying to this treatment the most keen criticism than by any hasty judgment either for or against the remedy. Dr. GOODALL claims the whole of this year for the inquiries necessary. We do not think

he is unreasonable, though he will understand the anxiety of the public for an answer when he remembers that the disease to be combated is nearly six times more fatal than scarlet fever. It is, indeed, not a little remarkable that as time goes on, and other diseases are brought into comparison with it, scarlet fever seems to become almost a mild disease. The mortality of the different infectious diseases treated in the hospitals in 1894 comes out as follows: that of scarlet fever, 5·92 per cent.; of diphtheria, 29·29 per cent.; of enteric fever, 18·13 per cent.; and of typhus fever, 16·67 per cent.

There seems, indeed, a danger that we should come to think too little of scarlet fever. It still constitutes the great bulk of the material of the work of these hospitals; but its comparatively low mortality and the somewhat sanguine estimate of what our enormous and costly isolation arrangements can do suggest the thought that it is in danger of being too lightly regarded. We may do well to remember that fluctuations in its mortality have always been recognised and that we may be now in the middle of a period of comparative mildness. As to the power of the system of isolation hospitals, one of the most respected medical superintendents, Dr. BIRDWOOD, goes so far as to say that the time has arrived when an attempt to exterminate scarlet fever might be made. It is always, of course, right to be attempting extermination, and every local curtailment of the disease shows how possible is its complete control. Such curtailment is by no means confined to the hospitals of the Asylums Board and is often to be seen in comparatively humble homes. But with such numbers as have strained the accommodation of the hospitals during the last two years, and with many instances of the apparent conveyance of the disease by patients returning home from the hospitals, it does seem a little premature to speak of the extermination of disease. The idea is, perhaps, more reasonable in regard to small-pox in the metropolis, the mortality from which sometimes reaches a vanishing point. Thus in 1838 the annual mortality from small-pox (see table on page 35 in the volume of these Reports) was 2161 per 1,000,000, in 1891 it was 2 per 1,000,000, and in 1894 20. But here we have means of control which we have not in scarlet fever. As examples of the concurrent incidence of two infectious diseases in the small-pox hospital ships no less than 44 cases of scarlet fever occurred in the course of the year. Dr. GOODALL states that 2 fatal cases of scarlet fever were complicated with puerperal fever on admission. Diphtheria still has an unpleasant tendency to occur in convalescents from scarlet fever in these hospitals, and at such a stage of the primary disease as to negative the idea of its having been contracted before admission. But on the whole the cases of this occurrence have been less frequent than in some previous years.

It is right that we should be reminded in these reports of the occurrence of errors of diagnosis. We have had occasion before to observe that the largest number of errors noticed was at the Eastern Hospital. The ascertained errors here were 3·7 per cent. of cases of certified scarlet fever, 17·5 per cent. of certified diphtheria, and 25·8 per cent. of enteric fever. The last is a large proportion of error, but it is touched upon kindly and somewhat apologetically.

by Dr. GOODALL, who remarks on the difficulty of an early diagnosis and the danger of a late removal. Granting that an early removal is desirable when the disease is ascertained, we still think that an error of 25 per cent. is one which should be largely reduced, and that while early diagnosis is an urgent duty there is no excuse for excessive haste. Some illustrations given of errors of diagnosis in small-pox are important. Eleven of these were—rötheln 2, varicella 2, measles 1, acne 1, impetigo 1, erythema 1, syphilide 1, exfoliative dermatitis 1, and no symptom of disease 1. In some cases the disease was not diagnosed. It would be wrong not to emphasise such facts and to impress on all medical men that, though errors of diagnosis are occasionally inevitable, they should be reduced to a minimum for the credit of the profession and the benefit of our patients. We cannot conclude our consideration of these reports without a word of praise for the care with which they are drawn up and a word of sympathy for the medical officers and the staff, who work at no small personal risk, as the reports show. The Chaplain of the South-Eastern Hospital died from scarlet fever, and Dr. MACCOMBIE was laid aside for four and a half months suffering from diphtheria.

THE approaching revision of the British Pharmacopœia and the arrangements connected therewith formed items of considerable interest at the recent meeting of the General Medical Council. Historically, the proceedings are well worth comparing with those of last November; but where so many points have been gracefully conceded it would serve no good purpose to revive recollections of discussions upon which we commented at the time. It is a far more gratifying task to consider the present arrangements for the performance of the onerous task of revision, and to pass briefly under review the various directions in which revision appears to be most needed.

At the outset it must be frankly admitted that the present Pharmacopœia was, at the time of its production, one of the most satisfactory works of its kind that has ever been issued in this country. Those who are prone to destructive criticism seem never to weary of pointing out errors, inconsistencies, or redundancies in the Pharmacopœia, but we imagine that there are few books—and certainly no scientific books—which could endure the close criticism of daily reference for ten years without possibilities of improvement or alteration being suggested in numerous directions. In these days every branch of science moves quickly; what was true or relatively true ten years ago is probably at variance with accepted theories of the present day, and therefore change is to be desired, and, indeed, welcomed, though the changes must be made with caution, and even with reverence. Wholesale changes, which would produce a new volume with no likeness to the existing Pharmacopœia, are to be deprecated, and are, indeed, impossible unless the whole object and scope of the book are to be altered—and this would manifestly be contrary to the Act which provides for the publication of the Pharmacopœia by the General Medical Council. It would be easy to carry the desire for change too far, and to spoil a book whose main faults are that it is ten years old and that it stands in need of revision. Many

chemical tests and some of the formulæ and nomenclature require to be brought up to date, while the botany, with which, in the medical profession, we have less concern, needs many changes. Some of the official preparations, even some of those included in the Addendum, appear not to have found favour with prescribers and dispensers, while numerous drugs which are still employed to some extent are generally believed to be wholly inert, and would scarcely be missed if they were silently dropped out.

The present arrangements for the revision do not indicate the probability of any revolutionary changes, while they seem eminently calculated to ensure accuracy, or at least to render the book representative of the most modern teaching and experience. We are glad to see that, as before, the President of the General Medical Council, Sir RICHARD QUAIN, is Chairman of the Pharmacopœia Committee; the committee now, however, comprises four English members, two Scotch, and two Irish. This extension of numbers is a satisfactory improvement on the formerly proposed smaller consultative subcommittee; the addition of new names will be pleasing to the respective divisions of the United Kingdom concerned, and should lead to due consideration of the divergencies of practice which are believed to exist. This committee is to have charge of all matters relating to the preparation and publication of the Pharmacopœia, and the appointment of Dr. TIBARD as secretary will, it is to be hoped, tend to ensure a due recognition of the requisite changes in the Pharmacopœia from the student's and from the examiner's point of view. It has often been urged that teaching does not form one of the objects of a pharmacopœia, but it is none the less true that the book in question constitutes the framework of all English books of materia medica; hence it is of much importance to consider how far changes may affect the teaching of the future. The appointment of Professor ATTFIELD as editor guarantees that the present general scope and arrangement will be retained; we have often commented favourably upon his work, especially in connexion with his annual reports upon the progress of pharmacy, which present one at least of the aspects under which the work of revision must necessarily be considered; these reports have indicated that no pharmaceutical criticisms have escaped his observation, and augur well for the accuracy of the volume in this respect. The chief change, however, in connexion with the revision is the intention to submit certain points to well-recognised authorities in their respective branches, who are to be asked to act as referees and to advise the committee upon numerous questions in which special knowledge of the highest kind seems essential. The names of Mr. THISELTON DYER and Mr. HOLMES as referees in botany, of Dr. THORPE or Dr. RUSSELL as referee in chemistry, and of Dr. LAUDER BRUNTON, Professor FRASER, and Professor WALTER SMITH as referees in pharmacology and therapeutics will sufficiently indicate the desire of the Pharmacopœia Committee to leave no stone unturned in the endeavour to render the revision as perfect as possible; and, at the same time, their position as referees shows that while there is every desire for accuracy there is equally no intention to arrange for the production of a volume in which any special branch of study should be

allowed an undue predominance. The amount of labour that must be expended is sufficiently shown by the report of the Pharmacopœia Committee.¹ As on a former occasion, the various medical authorities have been appealed to for information, and many have responded with "communications of great value." Evidence as to the relative frequency of employment of certain drugs and preparations has been furnished from two points of view, from a careful inquiry addressed to medical men and from a similar inquiry obtained from the Pharmaceutical Society. Communications have also been sent from the Colonies and from India. The committee of revision, therefore, has an enormous amount of material to deal with, and it is to be hoped that it will see its way clearly to winnowing the wheat from the chaff, and to utilising only those suggestions which appear to come with sufficient practical authority. In 1895 an independent spirit was maintained, and the committee did not follow implicitly all the suggestions which were made, whether for additions or for omissions, and we fully anticipate that a similar course will be now pursued, and that ultimately the bulk of the book will be found to have undergone no very great alteration. Rearrangement and condensation will probably suffice to afford space for the limited number of new drugs which have come into general use during the last ten years; hence it may be anticipated that the new Pharmacopœia will be found to be diminished rather than increased in size. The arrangements for revision and the amount of material already contributed and collected afford ample grounds for believing that Sir RICHARD QUAIN, in his presidential address, was not unduly sanguine in expressing his conviction that the forthcoming edition of the British Pharmacopœia would be "one worthy of the Council under whose direction it is issued."

Annotations.

"Ne quid nimis."

THE CASE OF SURGEON LEA, R.N.
